Abstract

In this study, the cohort-component method of population projection is used to project changes in the size of various groups at five-year intervals from 2005 to 2025 for each of North Dakota's 53 counties. The populations of interest in the study, seniors, the disabled, students age 5 to 19, and households without vehicles, traditionally face greater mobility challenges than other members of their community. The objective of the study is to generate data that will aid in future public transportation research and policymaking in the state.

The paper includes a summary of relevant, existing data to assist in the understanding of the current size and distribution of populations of interest in North Dakota. Next, the conceptual framework behind the cohort-component method of population projection and its mechanics are reviewed. Finally, projections of age-gender groups and mobility-challenged populations by county calculated at five-year intervals from 2005 to 2025 are presented.

Demographic Data and Mobility Research

The efficient delivery of public transportation requires knowledge of the physical location of individuals who may benefit from service. Furthermore, given the dynamic nature of modern society, the design and operation of public transportation systems, as well as their oversight, must take into account changes in their community to properly accommodate changing needs in the presence of limited resources.

In this study, the cohort-component method of population projection is used to project changes in the size of various groups in five-year increments from 2005 to 2025 for each of North Dakota's 53 counties. Knowledge of the size and distribution of these groups, seniors, students, the disabled, and those without vehicles, within the state should aid policy makers and community transportation managers design a public transportation system that meets the changing mobility needs of the state's residents. In addition to providing projections of the North Dakota's population, the model, once calibrated, can also be used to project populations for other U.S. counties with data available to the general public.

Population projections are made by a large numbers of organizations, most often government agencies. For example, North Dakota population projections by county from 2005 to 2020 were the subject of a 2002 study by Rathge, Clemenson, and Danielson. This study relies on more robust migration data which was made available only recently and accounts for data problems in a unique way. No previous study has projected the size of certain groups of people that are of specific interest to decision makers and researchers in public transportation in North Dakota.

This paper is divided into three parts. The first presents a current demographic profile of North Dakota which is valuable as a starting point for those unfamiliar with the size and distribution of subpopulations that traditionally face mobility challenges. This information is also needed to project future population sizes using the cohort-component method. The second section reviews the cohort-component method of population projection, the most common method used for calculating future populations. The third part of the paper presents the projected size of subpopulations of interest to public transportation researchers. Included as appendices are population projections by age and gender from 2005 to 2025 as well as for special population groups facing greater mobility challenges than the general population.

The geographic level of interest in the study is the county level. The reason for this is four-fold. First, as a rural state, many of North Dakota transportation providers serve large geographic, often multi-county, regions. Second, in many rural areas the efficiencies that may arise by coordinating service at the multi-county level are of importance. Thirdly, some of the data needed to project populations with the methodology used is not available at the local level. Finally, many of North Dakota's communities are so small that if the cohort-component were used at the sub-county level, illogical results would be generated.

Current Demographic Profile

An understanding of the current composition of North Dakota's 53 counties serves as a conceptual starting point for projecting populations. Data on total population, migration, births, deaths, and subpopulations are also needed as input for the cohort-component method. In this section data from the 2000 Census on total population, seniors, enrolled students, the disabled, households without vehicles, and minorities are presented. The number of net migrants between the years 1995 and 1999, data which was prepared in conjunction with the 2000 Census, is also included.

Total Population

North Dakota is a predominantly rural state. As can be seen in Figure 1, just over 50 percent of the state's 642,200 residents live outside its four largest counties. Of these four counties, three are classified as metropolitan areas meaning their urban center has 50,000 or more residents. These communities: Fargo-Moorhead, located in Cass County, N.D., and Clay County, Minn., Bismarck, located in Burleigh and Morton Counties, N.D., Grand Forks, located in Grand Forks County, N.D., and Polk County Minn., are the regional economic and cultural hubs of the state. Minot, a community of nearly 40,000 residents in Ward County, plays a similar role for northwest North Dakota.

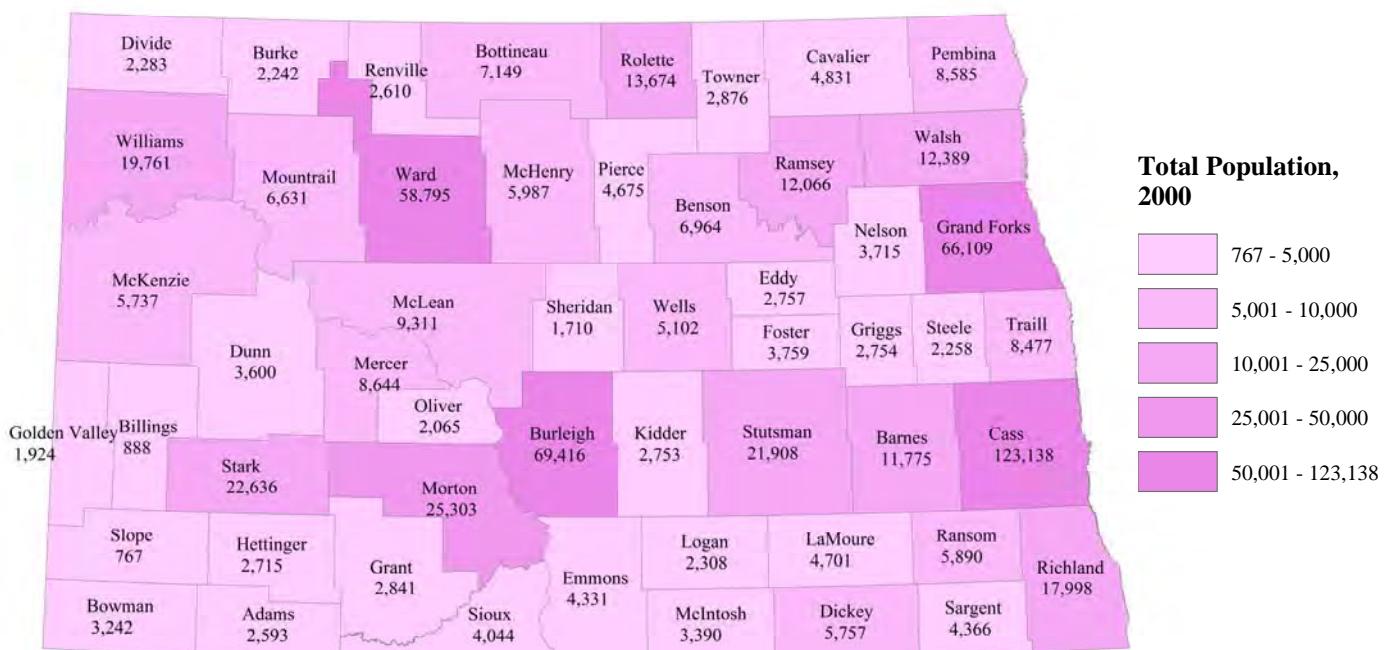

Figure 1. Population by County, 2000

During the 1990s, all but six of North Dakota's 53 counties lost population as shown by Figure 2. The six counties that saw an increase in population were either home to one of the state's largest cities or Native American reservations. Cass County saw by far the largest gain with an increase of 20,264 people, followed by Burleigh with 9,285. The counties of Rolette and Sioux, homes to the Turtle Mountain and Standing Rock Reservations, have younger populations than most other rural parts of the state, a higher birth rate, and lower migration rate than their neighbors and saw small increases in population in the 1990s. Grand Forks, which lost 4,574, 6.4 percent of its 1990 population, during the decade, suffered from both the realignment of the Grand Forks Air Force Base and the 1997 flood. Divide, Burke, Sheridan, Cavalier, and Hettinger counties lost more than 20 percent of their populations in 1990s.

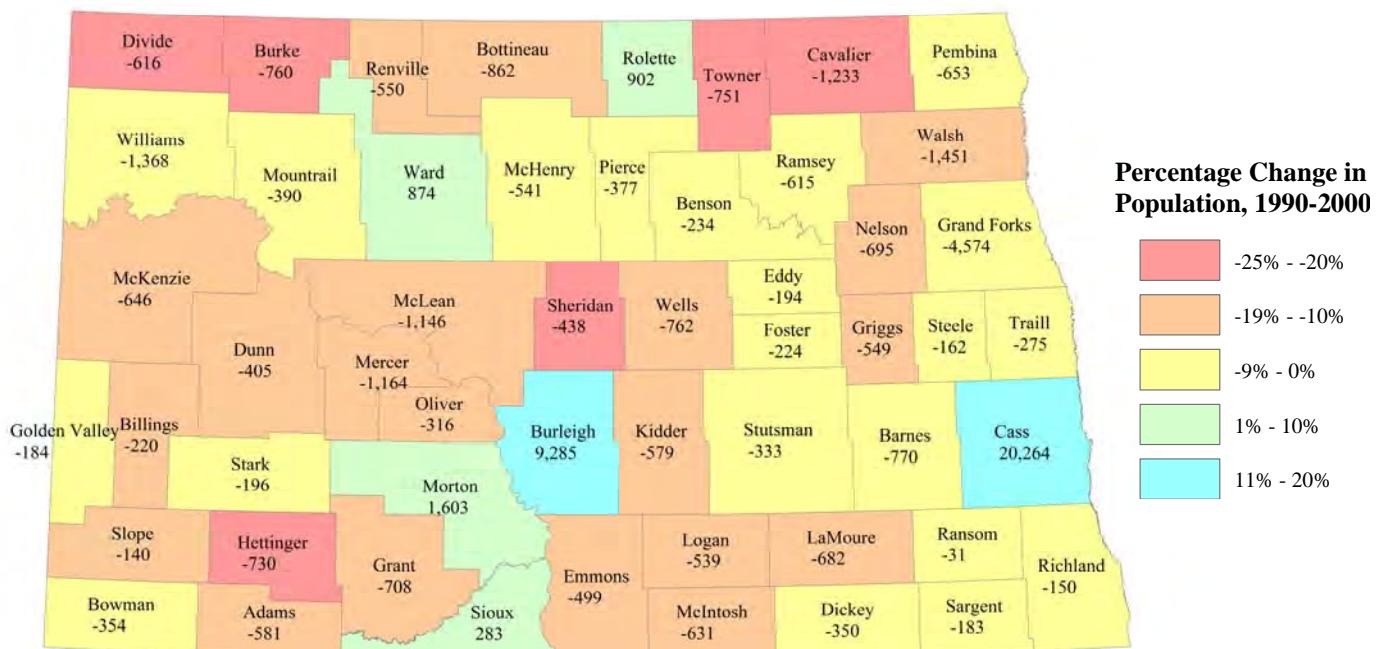

Figure 2. Population Change by County, 1990-2000

Migration

One of the primary drivers of the change in North Dakota's population is the out-migration of its residents. Though out-migration rates during the last five years of the 1990s were highest for North Dakota residents' age 15 to 30, significant numbers of North Dakotans from all age groups left the state. However, the loss of individuals age 15 to 30 has a greater impact on the state, especially in the long-run, as these are traditional childbearing years.

All but five counties saw negative net migration between 1995 and 1999 as can be seen in Figure 3. Grand Forks County lost 8,107 residents, followed by Ward County with 4,707. Much of the loss in population in Ward County can be attributed to the loss of missions at Minot Air Force Base. Relative to its size, only one county, Cass, saw a sizable positive net migration. Note that these numbers refer to county migration and that, in addition to migration out of the state, there were significant shifts of North Dakota residents within the state's borders.

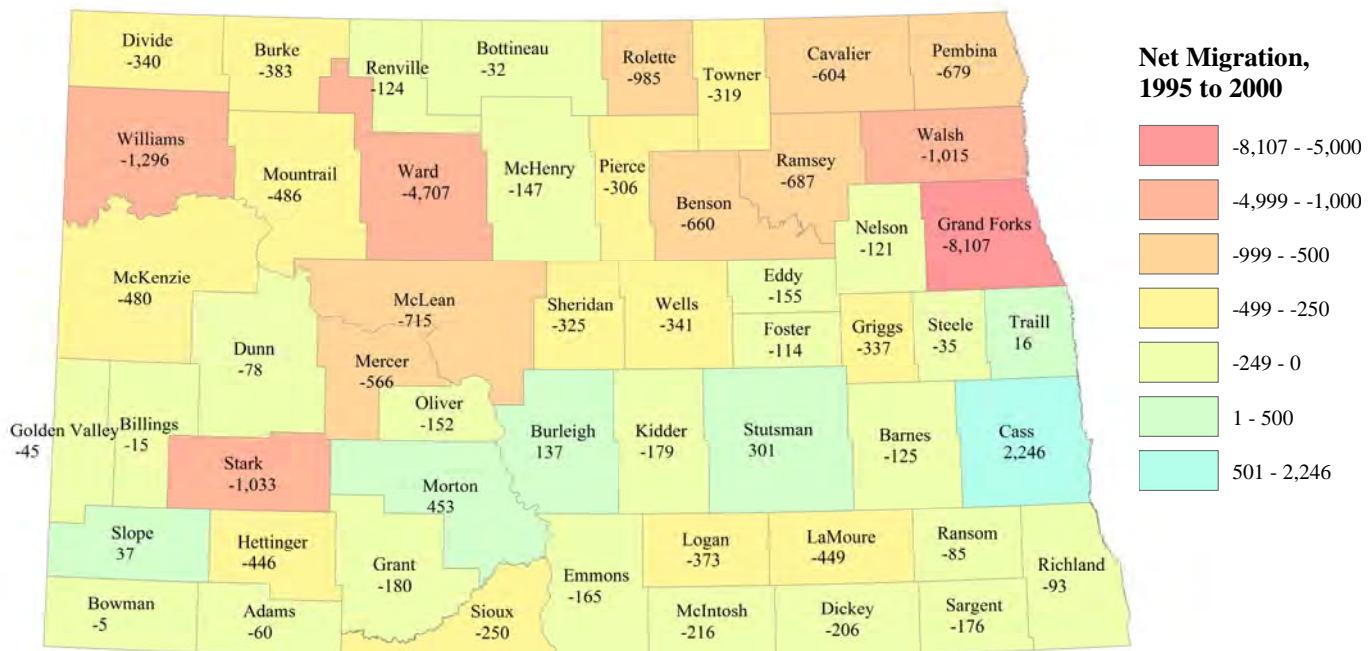

Figure 3. Net Migration by County, 1995-2000

Seniors

North Dakota has a relatively large senior population compared to the rest of the nation. The number of seniors in North Dakota by county in 2004 is presented in Figure 4. Seniors make up 14.7 percent of the state's population compared to 12.7 percent for the nation as a whole. These individuals are spread relatively uniformly throughout the state, with slightly more seniors residing in rural counties. In the urban counties of Burleigh, Cass, Grand Forks, and Ward seniors make up 12, 10, 10, and 12 percent of the population. More than one-quarter of the rural counties of Burke, Emmons, Griggs, Hettinger, Logan, Nelson, Sheridan, and Wells are seniors.

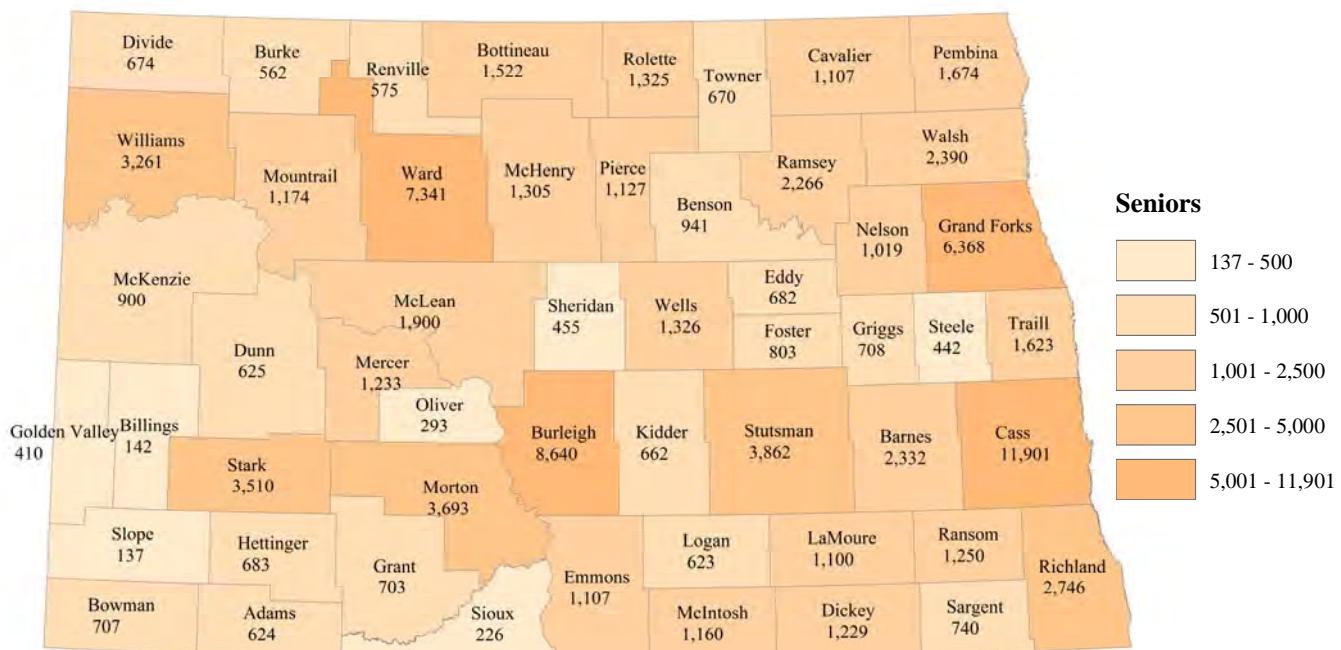

Figure 4. Senior Population by County, 2000

The Mobility-Impaired

The number of individuals with go-outside-the-home disabilities as identified by the 2000 Census is presented in Figure 5. The largest numbers of mobility-impaired residents can be found in the more populous counties. Note that there is a strong correlation between old age and the presence of disabilities that limit one's ability to live independently. Given that rural areas have relatively larger senior populations than urban ones they can also be expected to have a higher proportion of mobility-impaired residents. In North Dakota counties this relationship holds true.

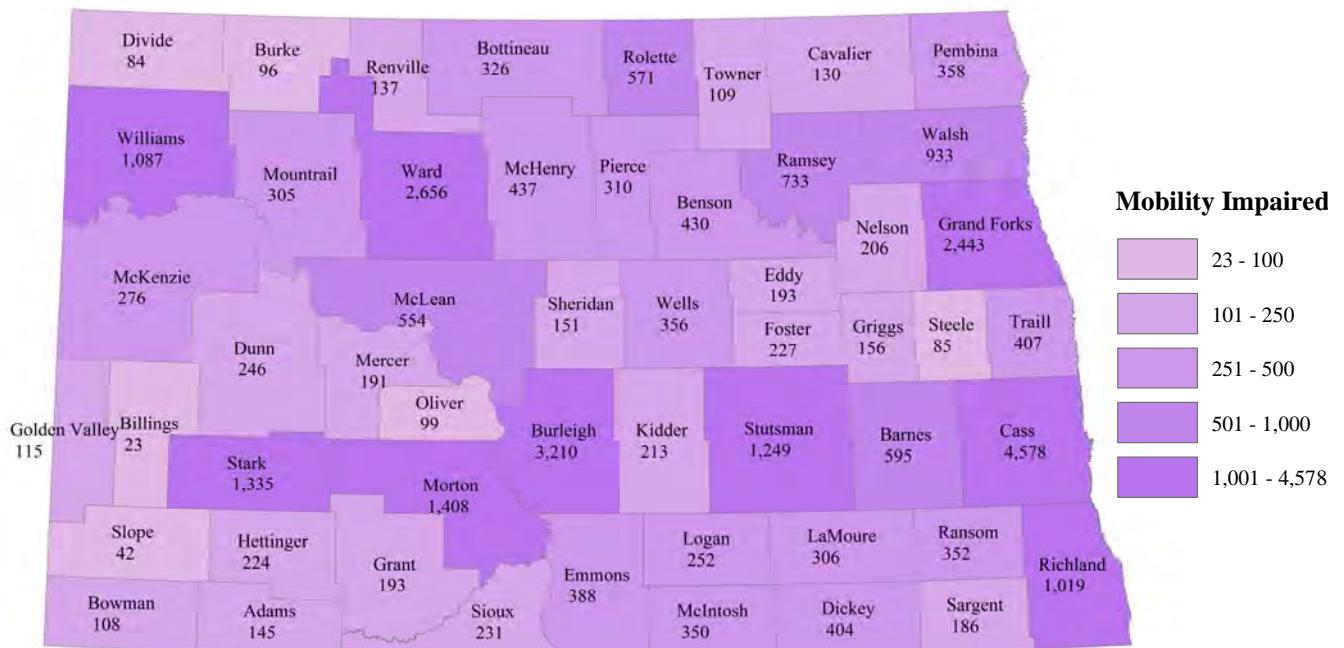

Figure 5. Mobility-Impaired Population by County, 2000

Students

The number of individuals age 5 to 19 that are enrolled in school in 2000 is presented in Figure 6. Given the large distances and low population densities in rural areas, the challenge facing education providers is great. Statewide, approximately 21 percent of the population is an enrolled student age 5 to 19. There is little variation in this statistic across counties, with the exception of Benson, McKenzie, Mercer, Rolette, and Sioux which all have more than one-quarter of their population in this category. Each of these counties, with the exception of Mercer, have large Native American populations. The counties with the largest numbers of students are Cass, Burleigh, Grand Forks, Ward, Morton, Williams, Stutsman, and Rolette.

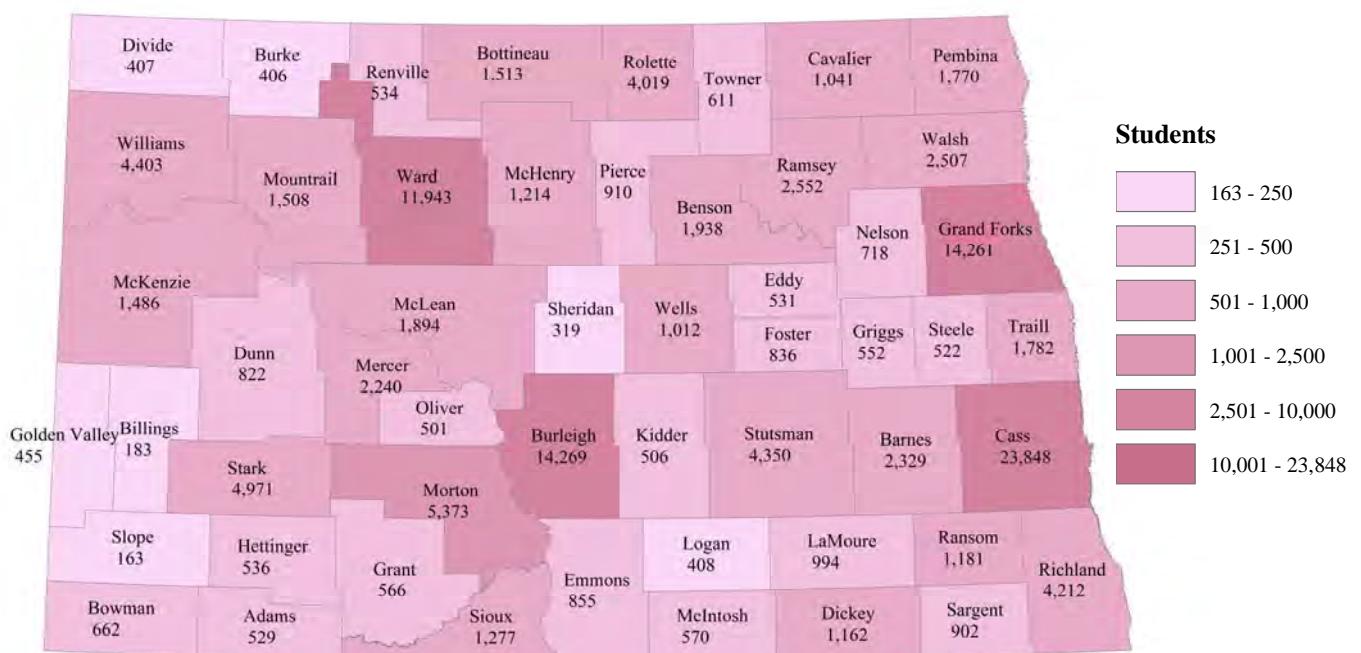

Figure 6. Enrolled Student Population Age 5 to 19 by County, 2000

Individuals without Vehicles

The number of households without vehicles in North Dakota is small compared with other parts of the nation, because of the need for mobility in rural areas. Figure 7 presents the number of households without vehicles by county. The counties with the largest numbers of households without vehicles are for the most part highly populated ones where community transportation services may satisfy individual's mobility needs. The rural counties of southwest North Dakota have very few households without vehicles; all Slope County households have vehicles.

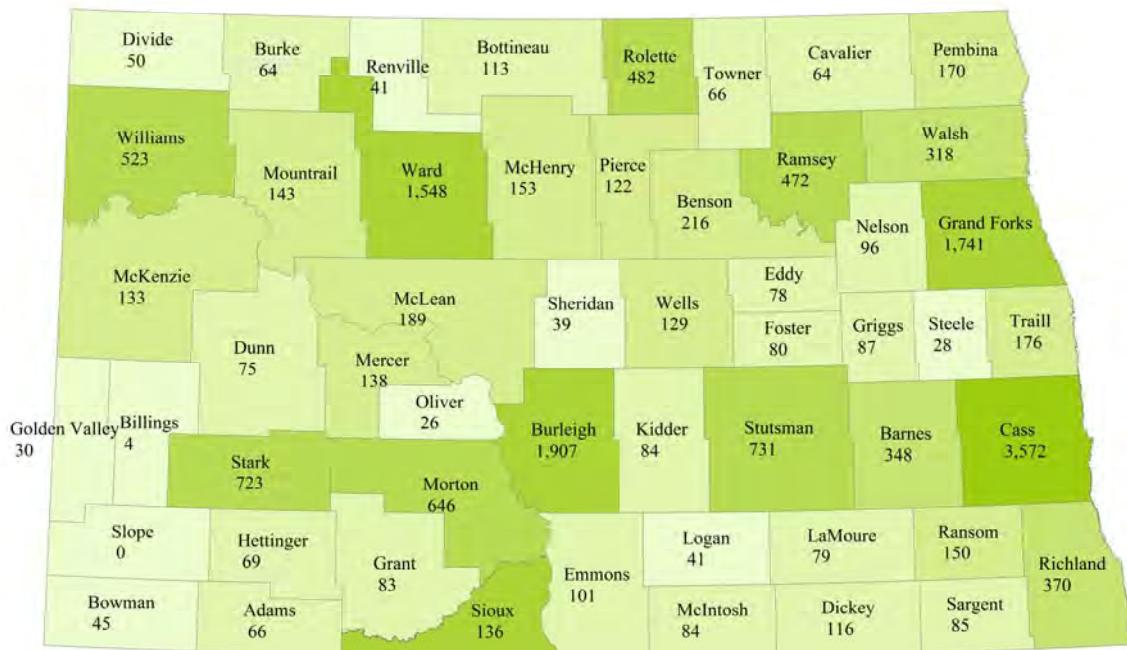

Figure 7. Number of Households without Vehicles by County, 2000

Minorities

Figure 8 presents the percent of the total population that is white in each county. The largest minority populations are located in Sioux, Rolette, and Benson counties which are each home to Native American Reservations. Sizeable minority populations are also found in Burleigh, Cass, Grand Forks, and Ward counties. The later two are home to Air Force bases that employ a number of military personnel that are racial minorities.

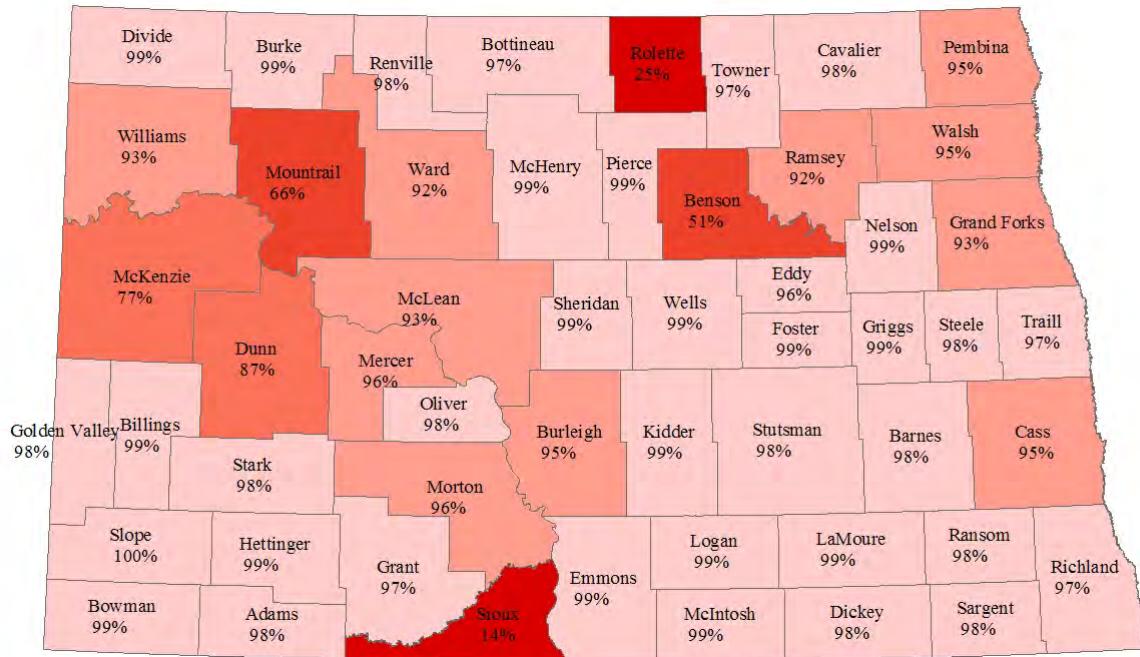

Figure 8. Percent of Total Population that is White by County, 2000

The Cohort-Component Method

The cohort-component method is the most commonly used technique to project future population size. The method, covered rigorously by Smith, Taymen, and Swanson (2001), is relatively standardized. However, small variations in the application of the method are often needed to account for the type of data available for input. One such modification was necessary for this study.

The basic concept behind the cohort-component method is that behaviors that prevailed recently will continue in the future. For example, if 10 percent of females age 25 to 29 moved out of a county during the last five-year period, it is expected that 10 percent of females in that age group in that county will do the same during the next five years. This assumption is quite strong and often erroneous. However, the results of the cohort-component method compare favorably to other methods of population projection.

Though not mandatory, most projections made using the cohort-component method use the date of census counts as starting, or launch, points. In this study, the launch date is the year 2000, the time of the last decennial census. Another subjective decision made by demographers who utilize the method is the determination of interval length, the time between the launch and target dates. Usually five year intervals are used. This occurs as most of the data needed to implement the cohort-component method that is freely available to the public is classified in five-year periods.

In the cohort-component method three components of change migration, birth, and death, drive changes in population from one period to the next. Projections are made for age-gender groups as migration and mortality rates tend to differ significantly by age and sex. Similarly, birth rates depend on the age of the potential mother. For the cohort-component method, the three components are addressed individually then combined to project the population.

A mastery of the notation used in population-projection models, which is relatively cumbersome, is needed to understand the mechanics behind the method and to properly build and use a population-projection model. Three symbols are used to manage the notation of time: the launch date, l , target date, t , and interval length, z . Individuals are grouped by their gender, g , and their age, where x is the youngest age in an age group and n is the number of years in each age group.

Migration

In- and out-migration rates are calculated for each age-gender combination using equations (1) and (2). The in-migration rate for individuals of gender g age x to $x + n$ during the period $l-t$ and l is found by dividing the number of individuals of gender g age $x + z$ to $x + z + n$ that move into the area during period $l-t$ to l by the number of individuals of gender g age x to $x + n$ that live outside the geographic region of interest at the beginning of the period, that is $l-t$.

This value is typically expressed as the difference between the total population of the United States of gender g age x to x +n, in year l-t less that residing in the region of interest.

$$(1) \quad {}_n INMIGRATE_{x,l-t \text{ to } l}^g = \frac{{}_n INMIG_{x+z,l-t \text{ to } l}^g}{{}_n USP_{x,l-t}^g - {}_n P_{x,l-t}^g}$$

The calculation of the out-migration rate is similar, with the exception that the population of the community of interest is the denominator (2).

$$(2) \quad {}_n OUTMIGRATE_{x,l-t \text{ to } t}^g = \frac{{}_n OUTMIG_{x+z,l-t \text{ to } l}^g}{{}_n P_{x,l-t}^g}$$

To project in-migration between the launch year, l, and the target date, t, the rate calculated in equation (1) is multiplied by the population of the United States less that of the community in the launch year (3) for each age-gender class. Similarly, out-migration is projected by multiplying the out-migration rate from (2) times the population by age-gender group at year l (4).

$$(3) \quad {}_n INMIG_{x+z,l \text{ to } t}^g = {}_n INMIGRATE_{x,l \text{ to } t}^g \times ({}_n USP_{x,l}^g - {}_n P_{x,l}^g)$$

$$(4) \quad {}_n OUTMIG_{x+z,l \text{ to } t}^g = {}_n OUTMIGRATE_{x,l \text{ to } t}^g \times {}_n P_{x,l}^g$$

Mortality

The second step in projecting population using the cohort-component method is to project the number of deaths for each age-gender group. Here the number of surviving individuals ${}_n SURVP_{x,l}^g$ is equal to the number of residents of gender g and age x to x + n at time l, ${}_n P_{x,l}^g$, times the survival rate for that age-sex combination ${}_n S_x^g$ (5). The survival rate can either be determined using site specific location or from state or national data. As survival rates are relatively uniform across the United States, use of national data is common as is the case in this study.

$$(5) \quad {}_n SURVP_{x,l}^g = {}_n P_{x,l}^g \times {}_n S_x^g$$

Natality

Next, the number of births for the region is projected. The first step in this process is to determine the age-specific birth rate, which is traditionally noted as births per 1,000 women in their childbearing years (ASBR). This is done by dividing the number of births born to a mother age x to $x + n$, ${}_n B_x$, divided by the total number of women in that age group, ${}_n FP_x$, and then multiplying that number by one thousand as shown in equation (6).

$$(6) \quad {}_n ASBR_{x,t} = \left(\frac{{}_n B_x}{{}_n FP_x} \right) 1000$$

To accommodate the fact that half of the women in an age group at the beginning of a period will pass into the next age group, the adjusted age-specific birth rate is needed. This is calculated by finding the arithmetic average of successive age-specific birth rates as shown in equation (7).

$$(7) \quad {}_n ADJASBR_{x,t} = ({}_n ASBR_{x,t} + {}_n ASBR_{x+z,t}) / 2$$

The number of women of childbearing age, referred to as the at-risk female population, is calculated using (8). This value is equal to the female population in the launch year plus immigrants, less the number projected to out-migrate or die. It is assumed that the women who die live for half of the interval.

$$(8) \quad {}_n ATRISK_{x,t} = {}_n P_{x,l}^f - .5 \times {}_n D_{x,l \text{ to } t}^f + {}_n INMIG_{x,l \text{ to } t}^f - {}_n OUTMIG_{x,l \text{ to } t}^f$$

The projected number of births between the launch and target years to mothers age x to $x + n$ is equal to the adjusted age-specific birthrate times the at-risk female population divided by one thousand (9). The total number of births is found by summing across all ages of mothers (10).

$$(9) \quad {}_n B_{x,l \text{ to } t} = {}_n ADJASBR_{x,t} \times {}_n ATRISK_{x,t} / 1000$$

$$(10) \quad B_{l \text{ to } t} = \sum_{\text{Ages}} {}_n B_{x,l \text{ to } t}$$

The total number of births, $B_{l \text{ to } t}$, is multiplied by rate of male births, $PCTM$, to determine the number of males born in the period, $MB_{l \text{ to } t}$ (11). Similarly, the number of births is multiplied by 1 minus the male birth rate to determine the number of females born, $FB_{l \text{ to } t}$ (12).

$$(11) \quad MB_{l \text{ to } t} = B_{l \text{ to } t} \times PCTM$$

$$(12) \quad FB_{l \text{ to } t} = B_{l \text{ to } t} \times (1 - PCTM)$$

These values are then multiplied by the gender-specific survival rate to project the number of male, $_n M_{0,z}$, and female, $_n F_{0,z}$, residents age zero to z in the geographic region (13,14).

$$(13) \quad _n M_{0,z} = MB_{l \text{ to } t} \times {}_n MS_0$$

$$(14) \quad {}_n F_{0,z} = FB_{l \text{ to } t} \times {}_n FS_0$$

Combining the Components

The determination of the projected value of the remaining age-sex groups is done by adding the surviving population with the number of in-migrants less the number of out-migrants as shown in (15).

$$(15) \quad {}_n P_{x+z,l \text{ to } t}^g = {}_n SURVP_{x+z,l \text{ to } t}^g + {}_n INMIG_{x+z,l \text{ to } t}^g - {}_n OUTMIG_{x+z,l \text{ to } t}^g$$

Projecting Special Populations

To project the population of individuals with trait γ , the ratio of individuals with the trait by age and gender to the total population of the gender-age group are calculated (16). To project the population, this rate is then multiplied by the projected population of that age-gender group calculated previously. The total number of individuals projected with trait γ is found by summing over age and gender (17).

$$(16) \quad {}_n \hat{P}_x^{g,\gamma} = {}_n P_{x,t}^{g,\gamma} / {}_n P_{x,t}^g$$

$$(17) \quad {}_n P_{x,t}^{\gamma} = \sum_g \sum_{ages} {}_n \hat{P}_x^{g,\gamma} \times {}_n P_{x+z,t}^g$$

To project the number of households with trait γ , it is further assumed that the household size will remain the same across time, a strong assumption. Household size is calculated by dividing the launch population by the number of households in the launch year (18). To project the number of households in the target year, the projected population in the target year is divided by this rate (19). Equations (20) and (21) project the number of households with trait γ in the same manner as (16) and (17).

$$(18) \quad \hat{H} = P_l / H_l$$

$$(19) \quad H_t = \frac{P_t}{\hat{H}}$$

$$(20) \quad \hat{H}^{\gamma} = H_l^{\gamma} / H_l$$

$$(21) \quad H_t^{\gamma} = \hat{H}^{\gamma} \times H_t$$

Data Requirements

To make use of the cohort component method, migration, mortality, natality (birth rate), and population data are needed. In- and out-migration data by county, age, and gender between the years 1995 and 1999 was taken from the U.S Census. Survival rates were taken from the National Center from Health Statistics. Birth data by age and county of mother was collected from the North Dakota Department of Vital Records. Total population data for the United States and each of North Dakota's counties by age and gender for 2000 were taken from the decennial census.

A modified estimate of U.S. population by age and gender for 1995 was calculated as the values provided by the U.S. Census proved to be out of sync when compared to the actual census counts taken in 2000. These estimates generated nonsensical projections. To address the issue, a 1995 estimate was generated using the 1990 and 2000 census counts and exponential growth between the two dates. This method resulted in significantly improved results, though the underlying theory behind its use is relatively weak.

Population Projections 2005 to 2025

The projected size and distribution of North Dakota's population varies greatly across groups from 2005 to 2025. The many unique phenomena projected to occur during this time period could be the subject of lengthy debate. Similarly, the data's implications with regard to public policymaking could fill volumes. The purpose of this study is to present the data generated and to leave commentary to future efforts.

In this section, a summary of the data generated by the model is presented. Appendix I includes state-level projections for each of the special populations of seniors, mobility-impaired, enrolled students age 5 to 19, and households without vehicles at five-year intervals from 2005 to 2025. It also includes the projections by age and sex for the same intervals. Appendix II includes this same data for each of North Dakota's 53 counties.

Figures 9 through 13 present projected populations for the years 2005 to 2025. As seen in Figure 9, North Dakota is projected to see a decrease in total population between 2000 and 2005, a relatively steady population for the next period, followed by a period of steady gain for the next 15 years. This change in direction of growth corresponds to the relative plateau of rural county populations reached after 2005 paired with the steady increase of urban county populations with occur throughout the projection periods.

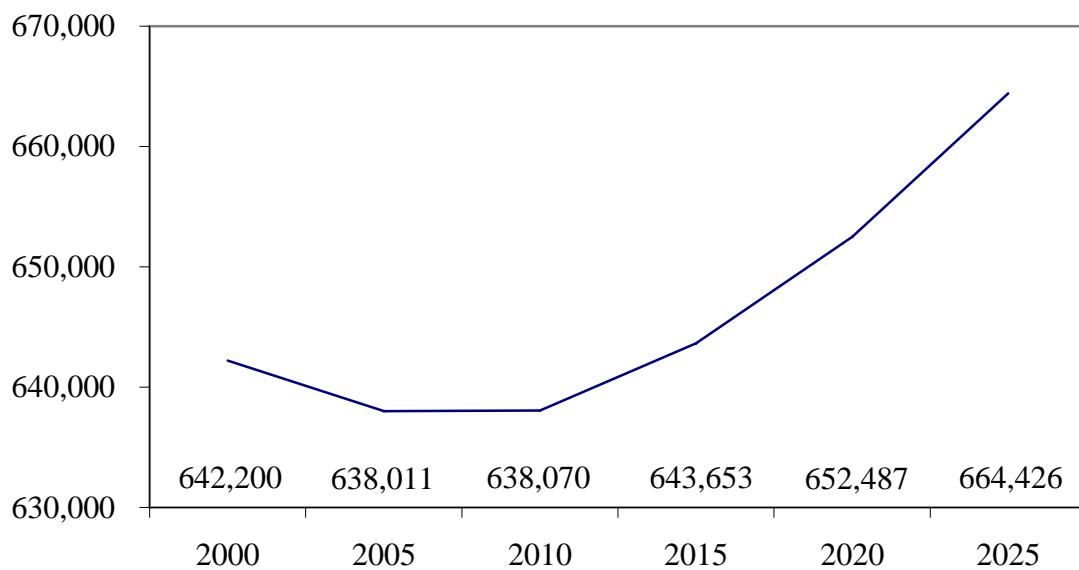

Figure 9. Projected North Dakota Population, 2000-2025

The projected number of seniors in North Dakota from 2005 to 2025 is presented in Figure 10. The number of elderly is projected to increase dramatically over the next 25 years from 94,478 in 2000 to 140,005 in 2025. Given the relatively small projected increase in the total population of the state as seen in Figure 9 the proportion of elderly is projected to increase tremendously.

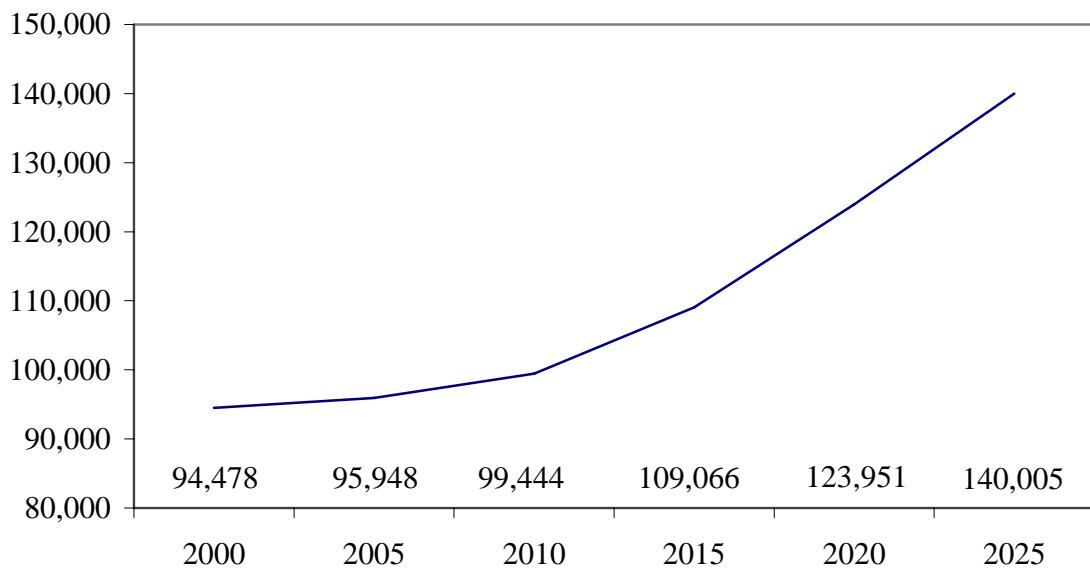

Figure 10. Projected North Dakota Senior Population, 2000-2025

The projected number of North Dakotans age 5 to 19 enrolled as students is presented in Figure 11. The number of students is projected to decline from its value of 135,053 in 2000 to 103,609 in 2015. Between 2015 and 2025 it is projected to increase by roughly 5,000.

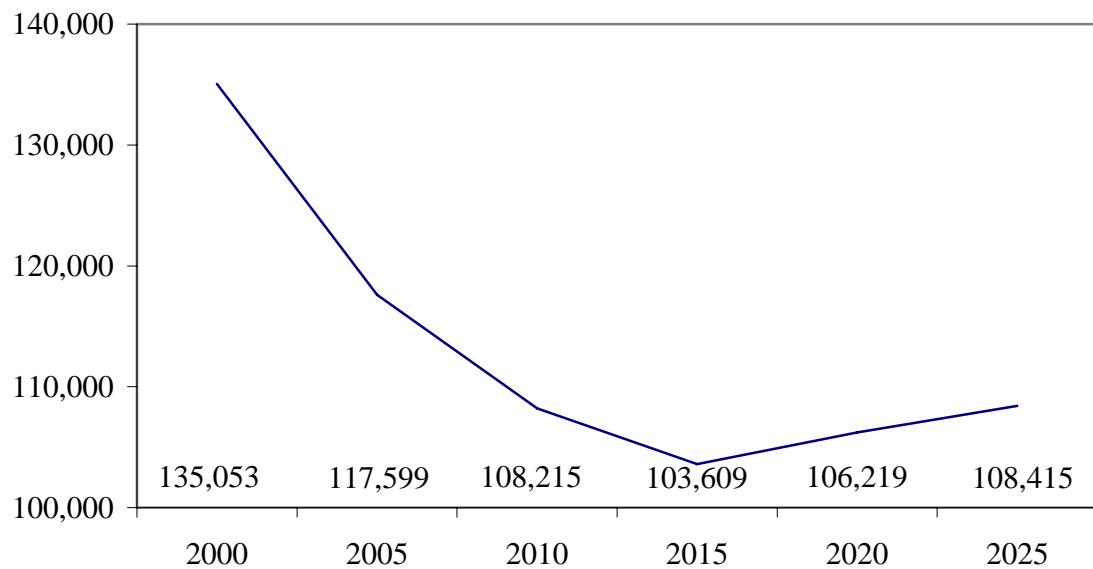

Figure 11. Projected North Dakota Enrolled Student Population Age 5 to 19, 2000-2025

The number of mobility-impaired North Dakotans, presented in Figure 12, is projected to increase significantly over the next 20 years. Given the large percentage of seniors who have one or more go-outside-the-home disabilities and the projected increase in the number of seniors, shown in Figure 10, the behavior is partially explained.

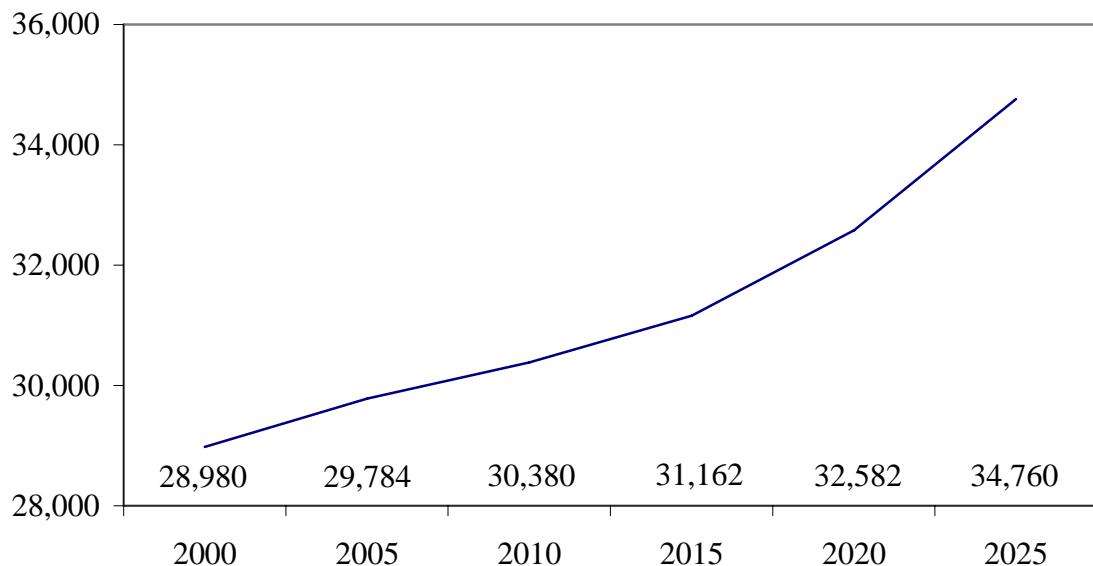

Figure 12. Projected North Dakota Mobility-Impaired Population, 2000-2025

The number of household without vehicles is projected to increase only slightly over the next 25 years from 17,030 to 17,784 as shown in Figure 13.

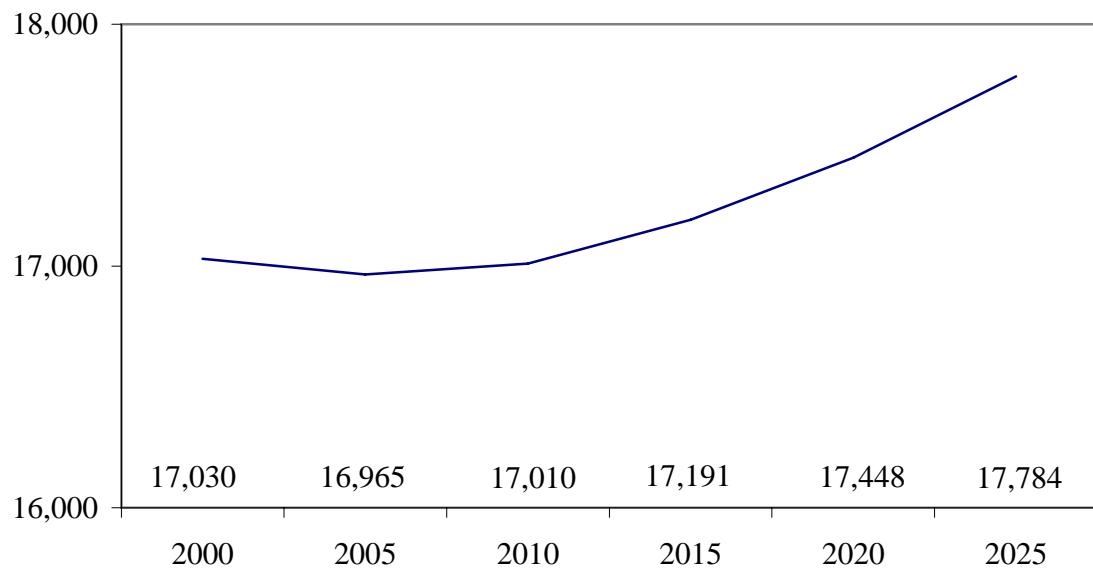

Figure 13. Projected Number of Households without Vehicles, 2000-2025

2010 Projections

The projected changes in North Dakota's population between 2000 and 2010 vary greatly by group. Though the state is projected to lose 4,130 residents during the period, the number of seniors is expected to grow by nearly 5,000. Also significant is the projected loss of 26,838 residents age 5 to 19 that are enrolled in school. The number of households without vehicles is expected to decrease by 20.

Ten counties are projected to experience population growth between 2000 and 2010. This includes Cass, Burleigh, Morton, and Sioux which also experienced net gains in the 1990s. They are joined by Traill and Richland Counties in the Red River Valley, Stutsman in east central North Dakota and Dunn, Billings, and Slope in western North Dakota. Barnes County just west of Cass is only projected to lose four residents.

Divide, Burke, Logan, and Hettinger Counties are expected to lose more than 20 percent of their population in the 10-year period. Grand Forks is projected to have the largest net loss of residents, 3,705.

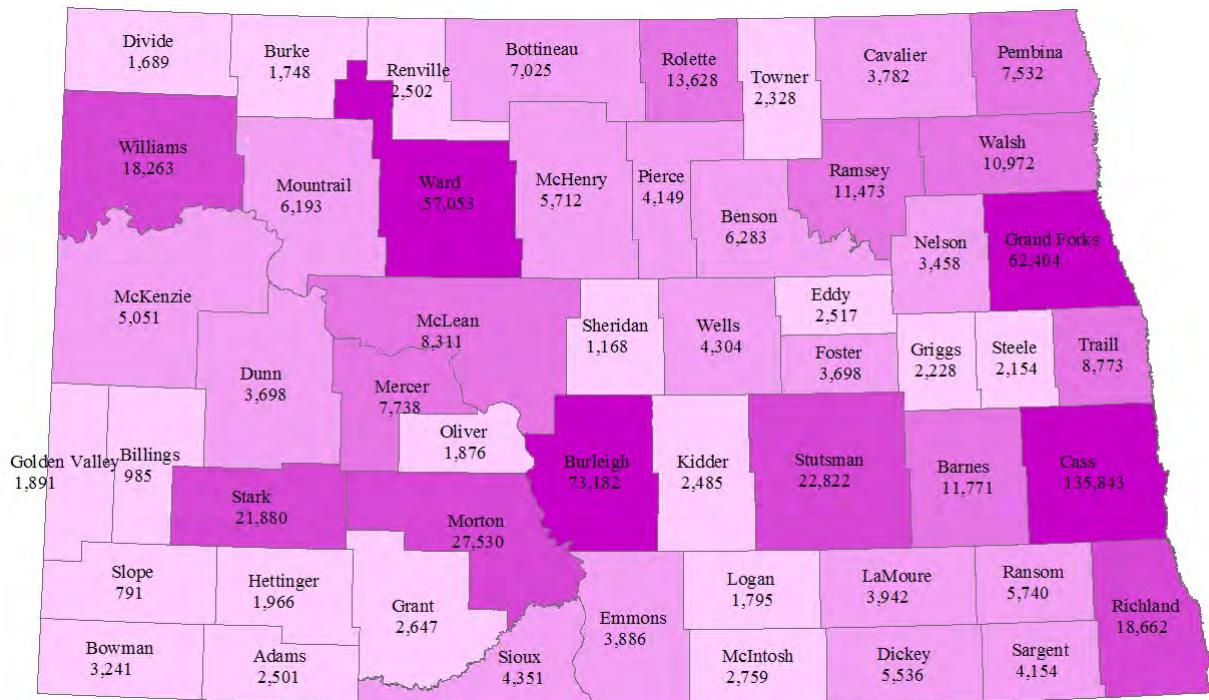

Figure 14. Projected Population by County, 2010

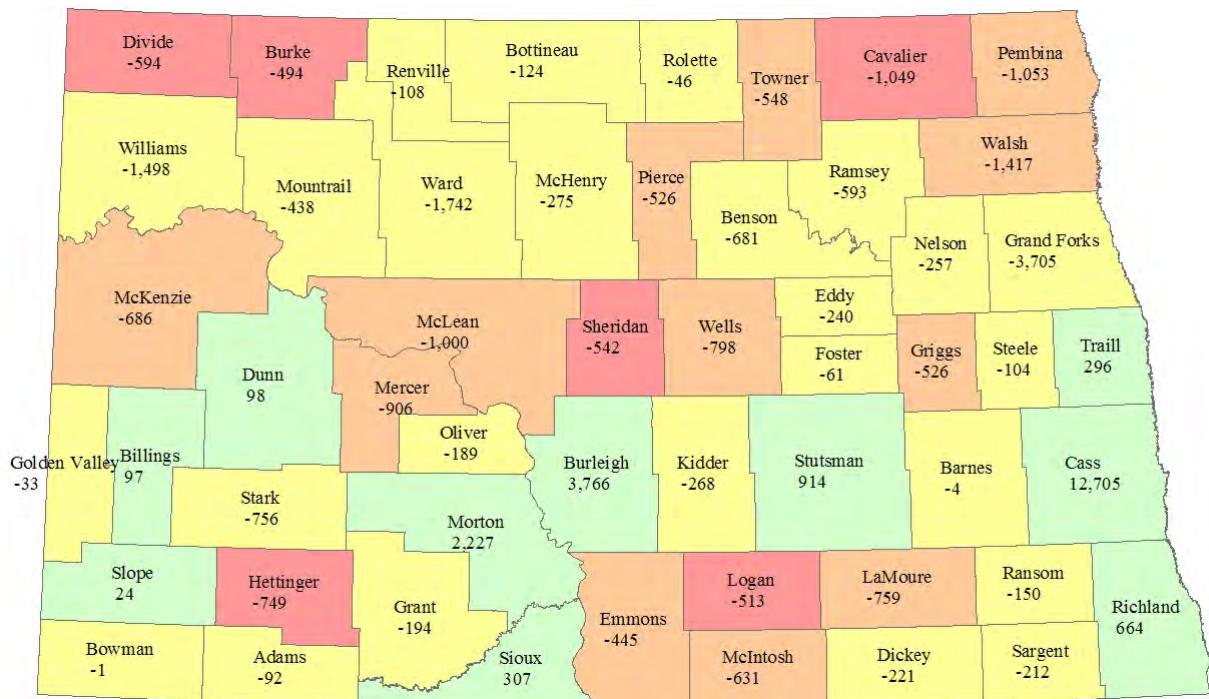

Figure 15. Projected Population Change by County, 2000 to 2010

The projected number of seniors in 2010 is presented in Figure 16 and the projected change in the number of seniors between 2000 and 2010 is in Figure 17. Twenty of North Dakota's 53 counties are projected to see an increase in their senior populations. However 16 of these 20 are expected to see an increase of less than 100 residents aged 65 or older. Cass County is projected to see an increase in its senior population of 1,964; Burleigh County, 1,846.

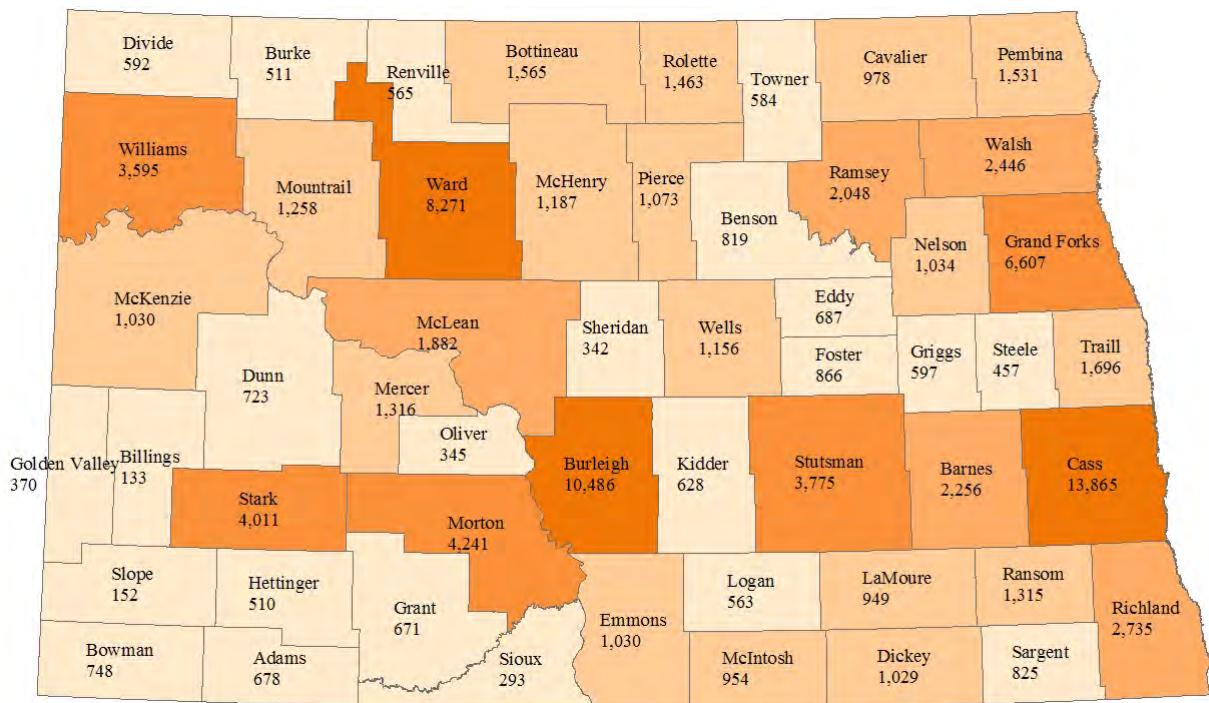

Figure 16. Projected Senior Population by County, 2010

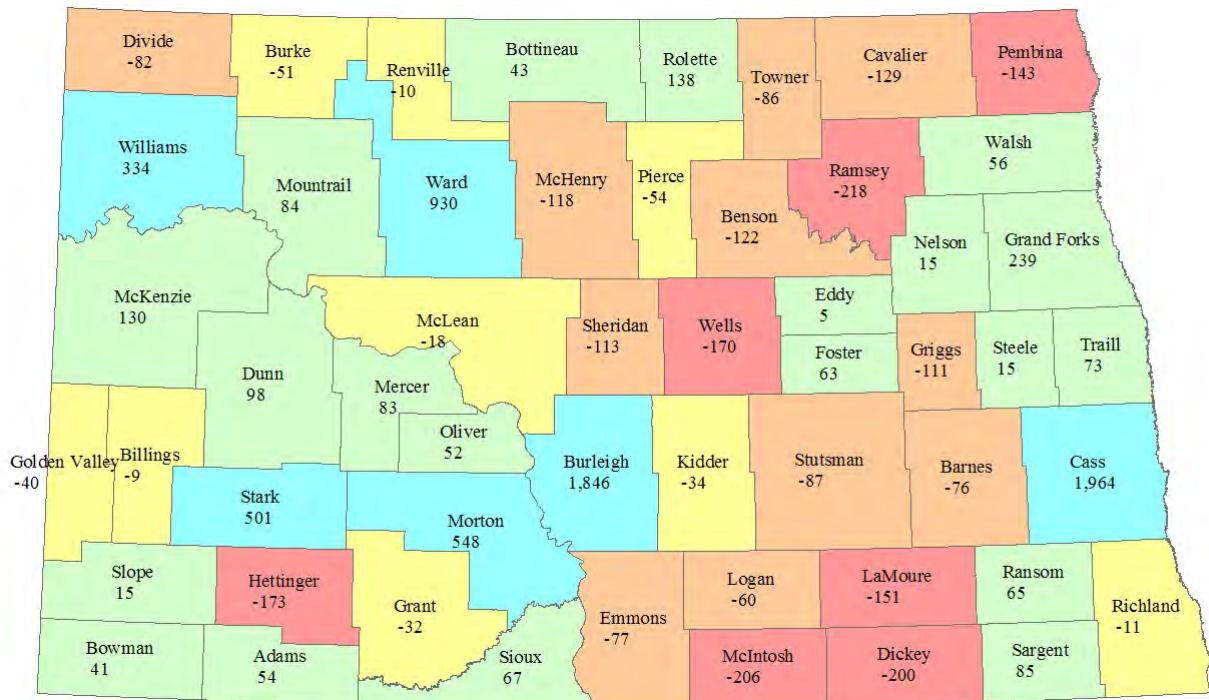

Figure 17. Projected Senior Population Change by County, 2000 to 2010

Figure 18 presents the number of projected mobility-impaired individuals in 2010. The projected change in the number of mobility-impaired individuals between 2000 and 2010 is presented in Figure 19. Roughly half of North Dakota's counties are expected to see an increase in the number of residents with a mobility-challenging disability. Cass and Burleigh counties are expected to see increases of 697 and 497 residents who have such disabilities, the changes in North Dakota's other counties are projected to be significantly smaller.

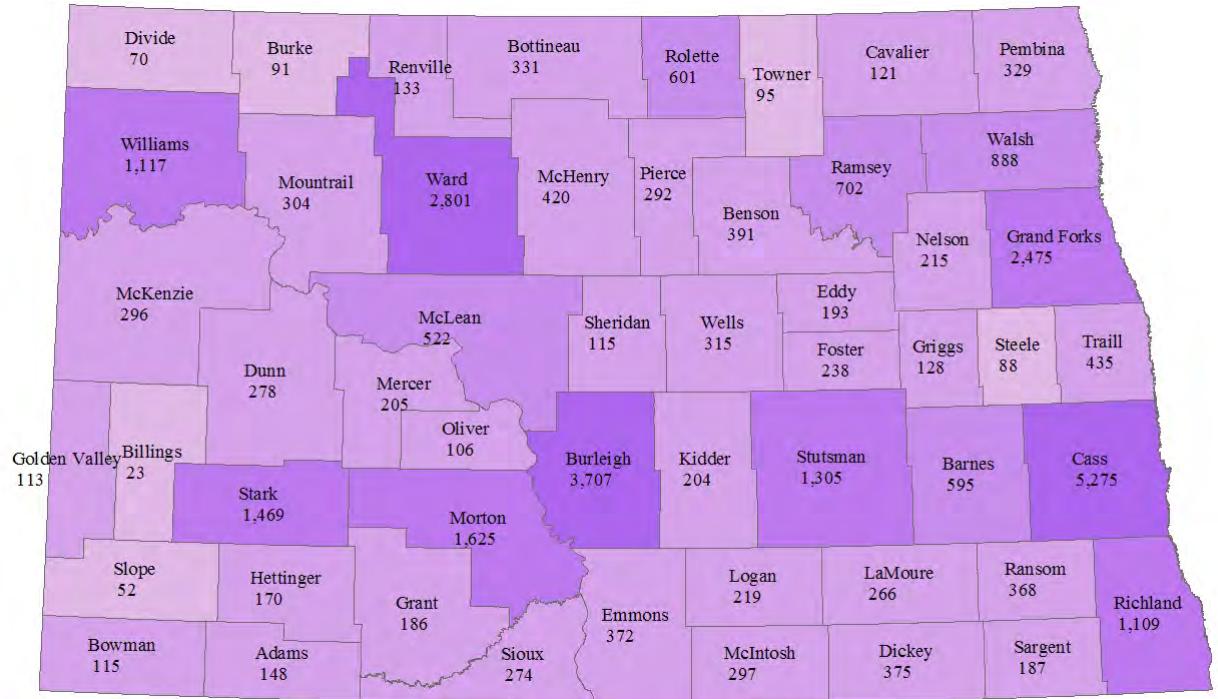

Figure 18. Projected Mobility-Impaired Population by County, 2010

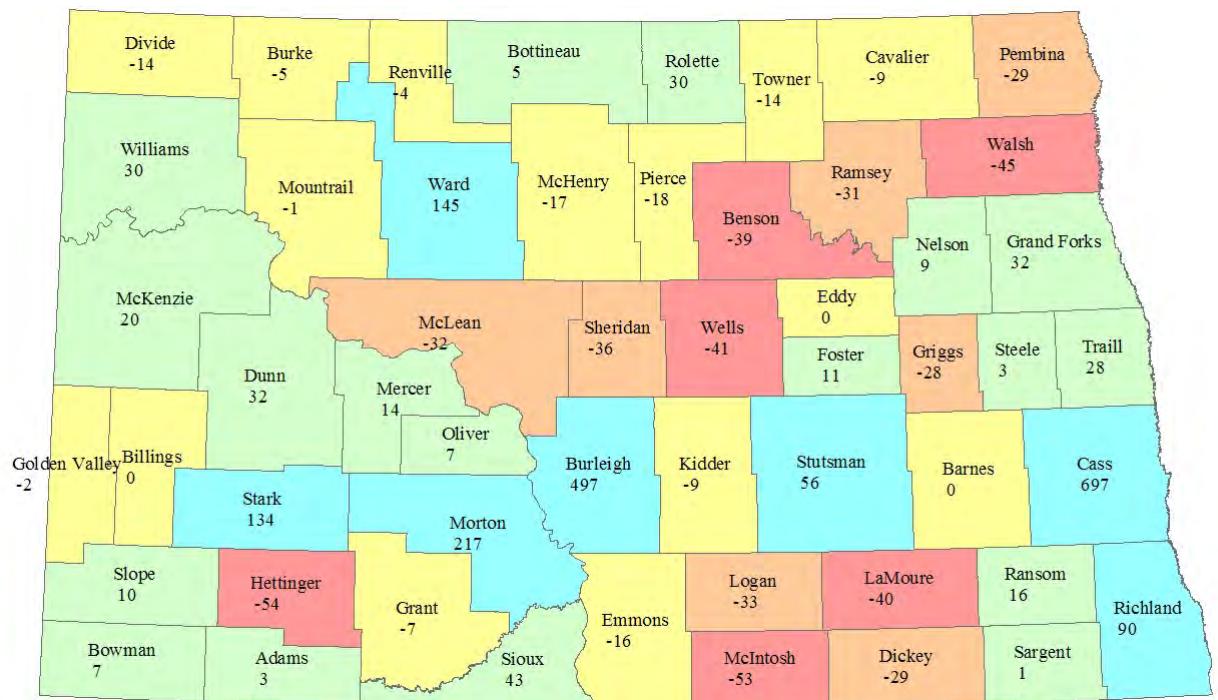

Figure 19. Projected Mobility-Impaired Population Change by County, 2000 to 2010

The projected number of enrolled students age 5 to 19 and the projected change in this population between 2000 and 2010 are presented in Figures 20 and 21. During this period, each of North Dakota's 53 counties is projected to lose enrolled students. The greatest losses are expected to occur in the state's largest counties. Cass, Ward, Burleigh, Grand Forks, Williams, Stark, and Richland counties are projected to lose 1,000 or more residents age 5 to 19 who are enrolled in school. The largest losses, in absolute terms, are expected in Grand Forks, Ward, and Burleigh counties where 4,387, 2,344, and 2,300 fewer students are expected.

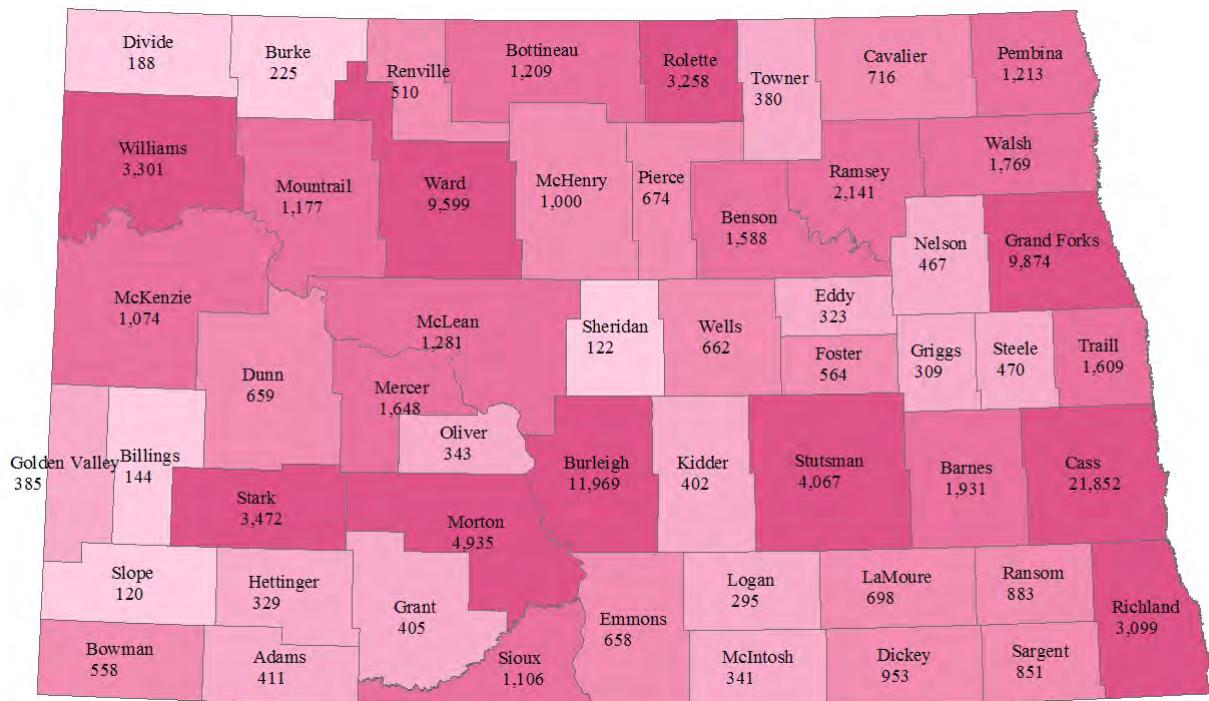

Figure 20. Projected Enrolled Student Population Age 5 to 19 by County, 2010

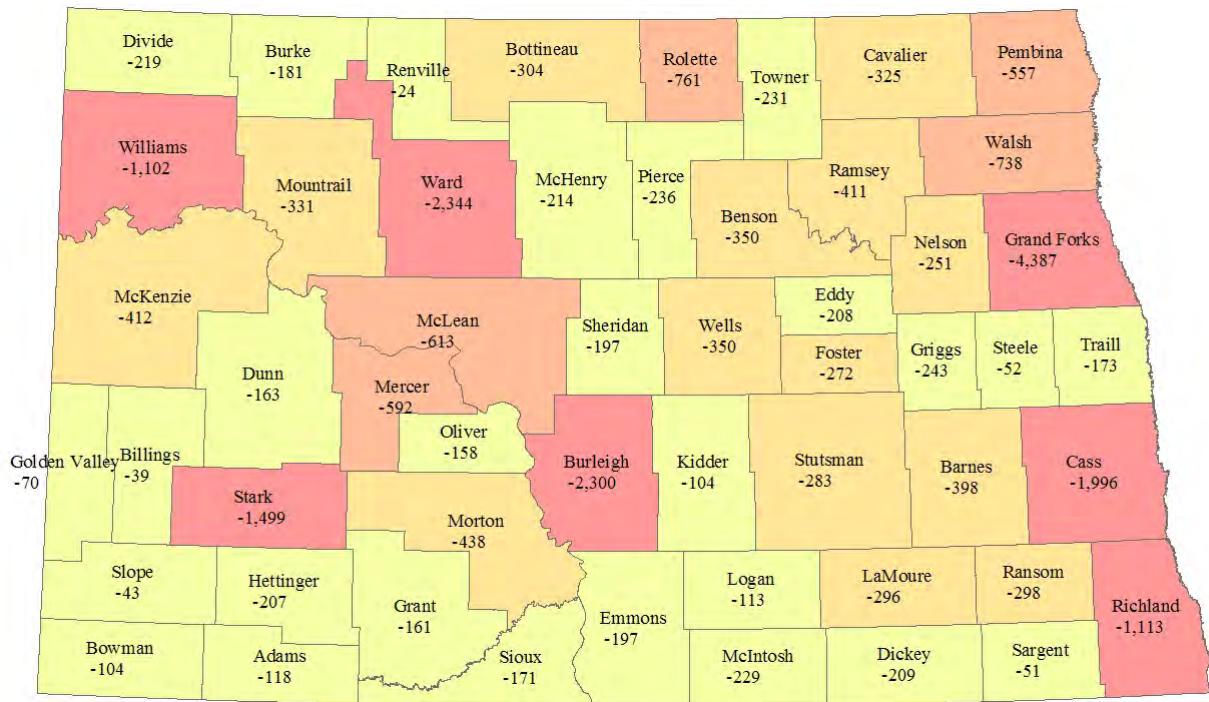

Figure 21. Projected Change in Enrolled Student Population Age 5 to 19 by County, 2000 to 2010

The projected number of households without vehicles by county in 2010 is presented in Figure 22. The projected change in the number of households without vehicles by county between 2000 and 2010 is shown in Figure 23. Fifteen counties are projected to see an increase in the number of households that do not have vehicles. However, most counties are projected to see relatively small changes with only Cass and Burleigh counties seeing increases of more than 100 households, while Grand Forks is the only county projected to see a decrease of more than 50.

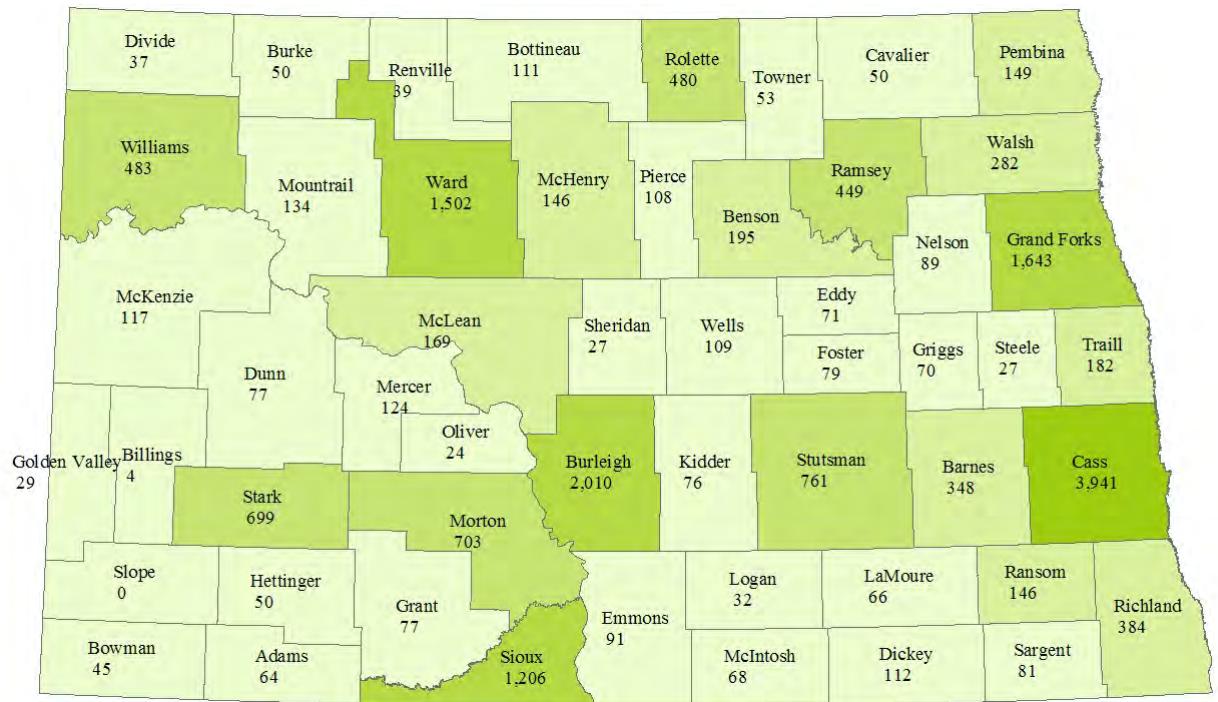

Figure 22. Projected Number of Households without Vehicles by County, 2010

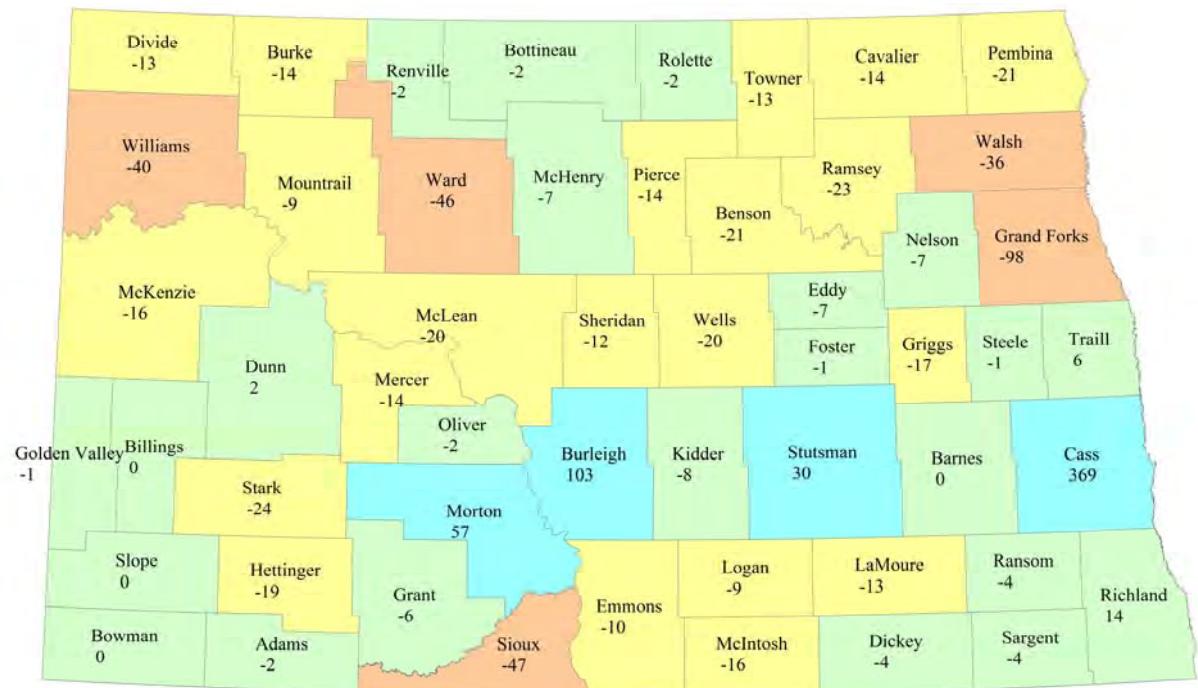

Figure 23. Projected Change in Number of Households without Vehicles by County, 2000 to 2010

2025 Projections

The projected direction and magnitude of change in populations between 2000 and 2010 are not, in general, projected to repeat themselves between 2000 and 2025. Though the state is projected to lose roughly 4,000 people between 2000 and 2010 it is expected to gain 22,000 residents during the first quarter of the 21st century. Looking more closely at the county level, the underlying dynamics causing this change are easily identified. Most rural county populations are projected to stay relatively steady between 2010 and 2025 while urban populations are projected to continue to grow. The number of seniors is expected to increase at an increasing rate between 2000 and 2025 from 94,478 to 140,005. The number of enrolled students is expected to level off after a precipitous loss between 2000 and 2010, increasing by only 200 from 2010 to 2025. The number of mobility-impaired residents is expected to increase at a relatively steady rate between 2000 and 2025 from 28,980 to 34,760.

Figures 24 and 25 present the projected total population in 2025 and the projected change in population between 2000 and 2025. Fifteen counties are projected to see an increase in population between 2000 and 2025. Cass and Burleigh counties are both projected to see increases in population of more than 10,000 individuals. Counties in southwest North Dakota are expected to see only slight increases in population. Grand Forks County is projected to lose 4,171 residents; Walsh and Williams counties more than 2,000; and Cavalier, Pembina, McLean, Mercer, Hettinger, Wells, LaMoure, McKenzie, and McIntosh counties more than 1,000.

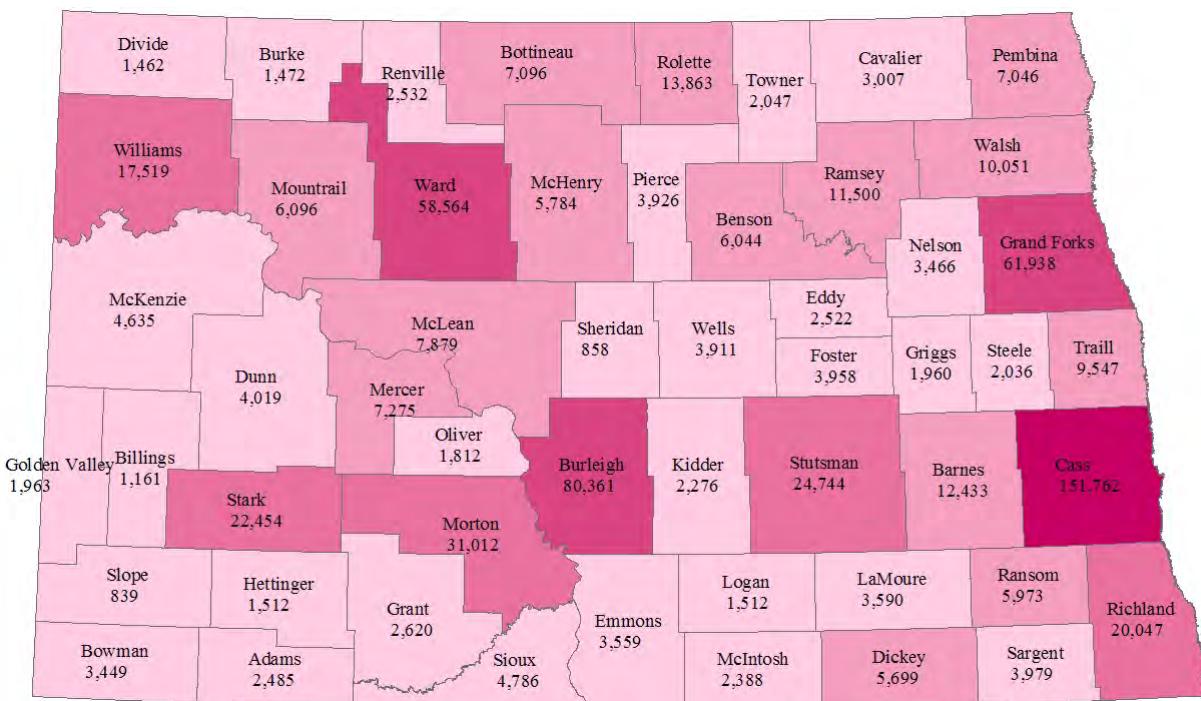

Figure 24. Projected Population by County, 2025

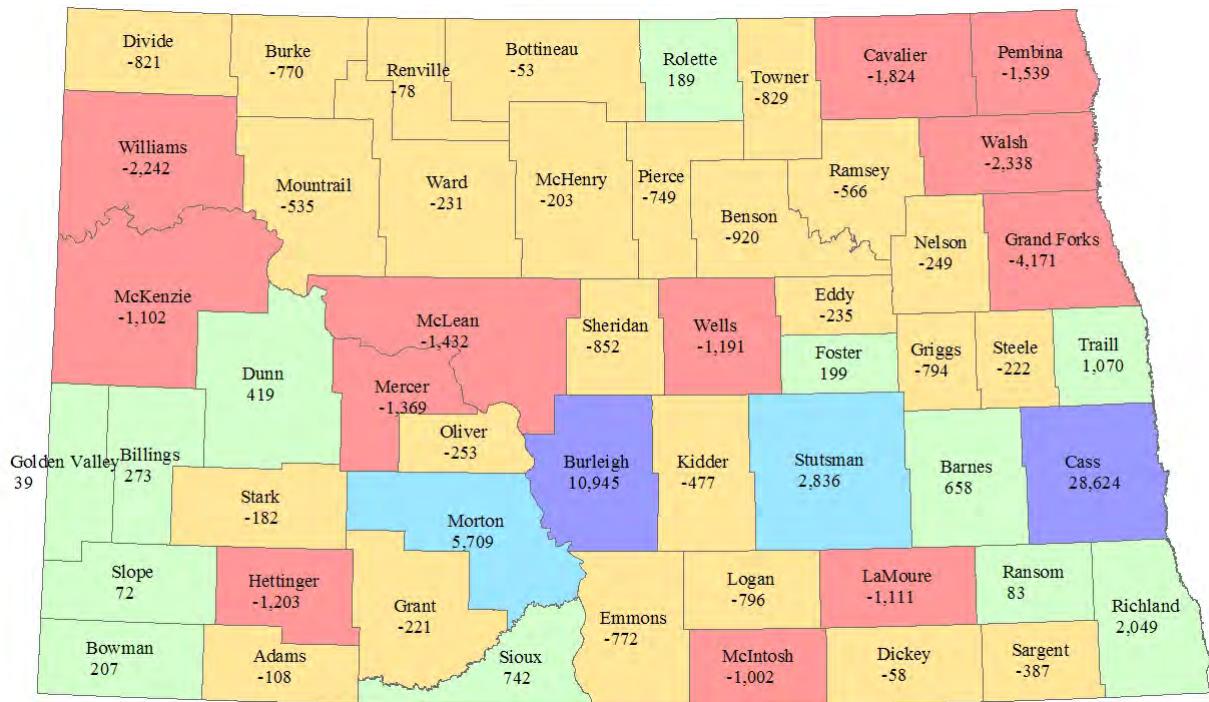

Figure 25. Projected Population Change by County, 2000 to 2025

The projected senior population by county in 2025 and the projected change in senior population between 2000 and 2025 are presented in Figure 26 and Figure 27. Only nine counties are projected to have a decrease in the number of seniors and five of these counties expect to lose more than 100 seniors. The number of seniors is projected to increase most notably in urban counties. Cass is projected to see an increase in 11,259 seniors; Burleigh 8,372; Ward 4,436 and Grand Forks 2,842. Gains of more than 1,000 seniors are also expected in Stark, Williams, and Stutsman counties.

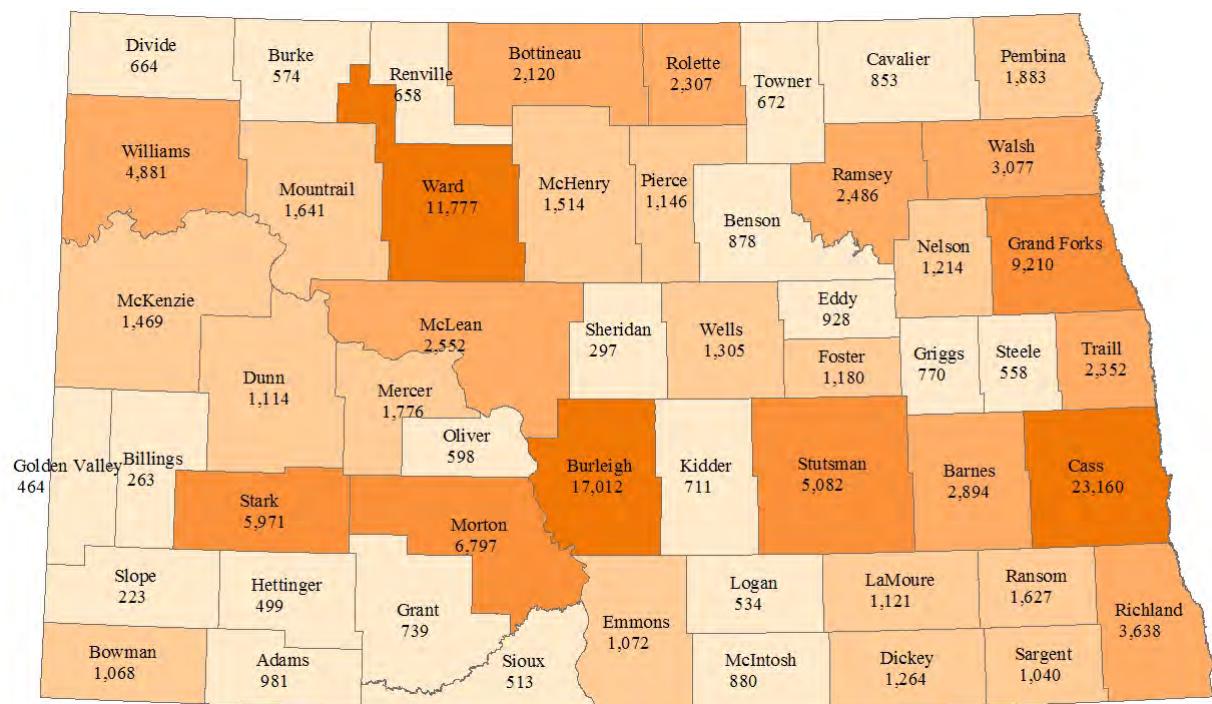

Figure 26. Projected Senior Population by County, 2025

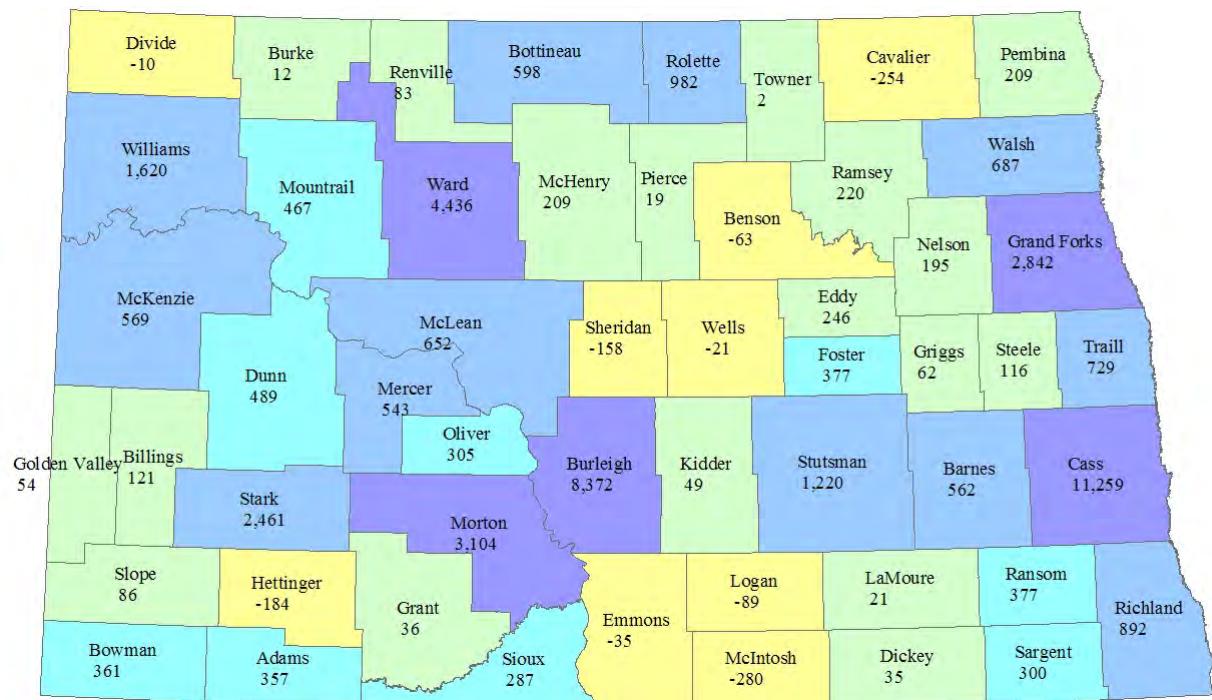

Figure 27. Projected Senior Population Change by County, 2000 to 2025

Figures 28 and 29 present the projected number of enrolled students age 5 to 19 in 2025 and the projected change in the same population from 2000 to 2025. All counties but one, Renville County in northwest North Dakota, are expected to see a loss of students between 2000 and 2025. Grand Forks, Ward, Burleigh, Williams, Richland, and Walsh counties are projected to have at least 1,000 fewer students enrolled in 2025 versus 2000.

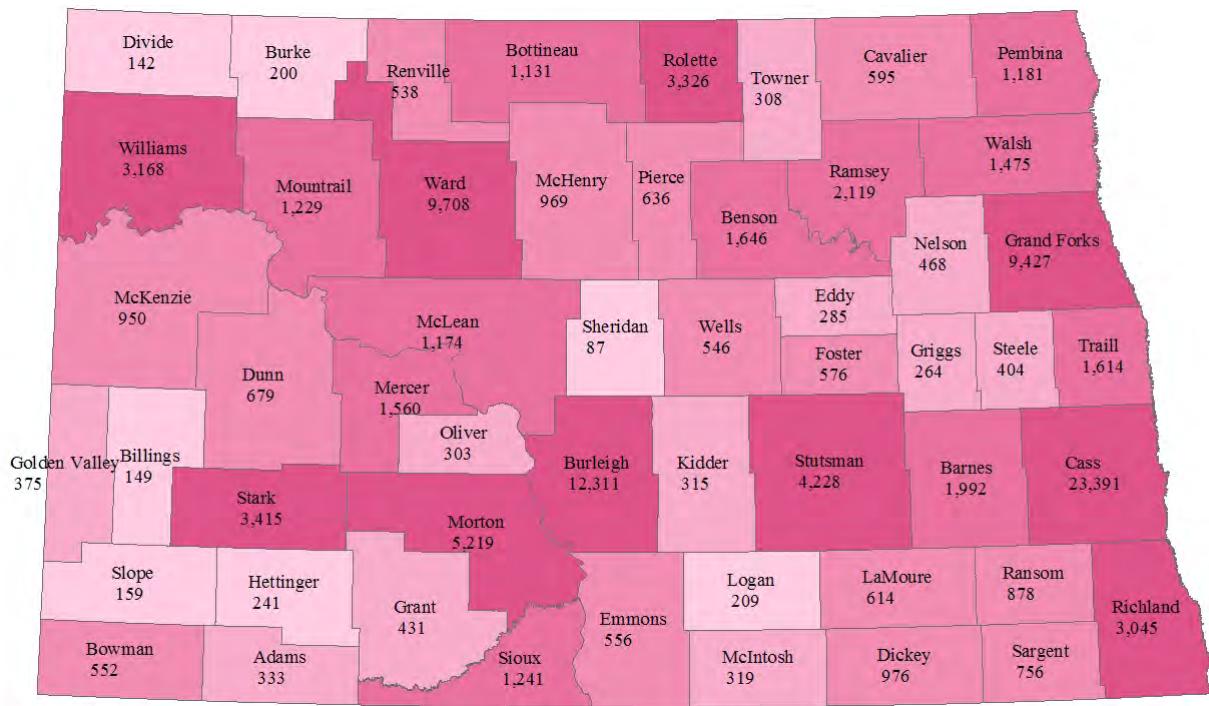

Figure 28. Projected Enrolled Student Population Age 5 to 19 by County, 2025

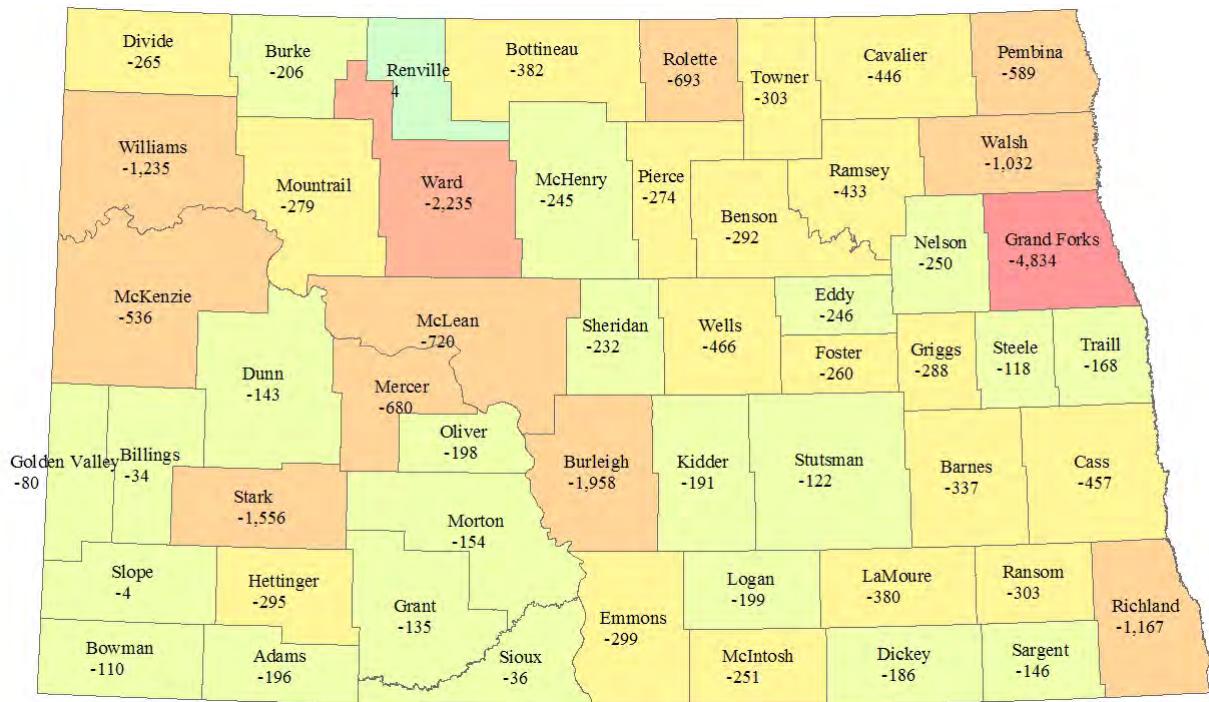

Figure 29. Projected Change in Enrolled Student Population Age 5 to 19 by County, 2000 to 2025

The projected number of mobility-impaired individuals in 2025 and the projected change in mobility-impaired residents from 2000 to 2025 are presented in Figures 30 and 31. Twenty one counties are projected to see a decrease in the number of mobility-impaired residents. However, only one of these counties, McIntosh, is expected to see a decrease of more than 100 mobility-impaired residents. Relatively significant gains are projected for Ward, Burleigh, Cass and Morton counties.

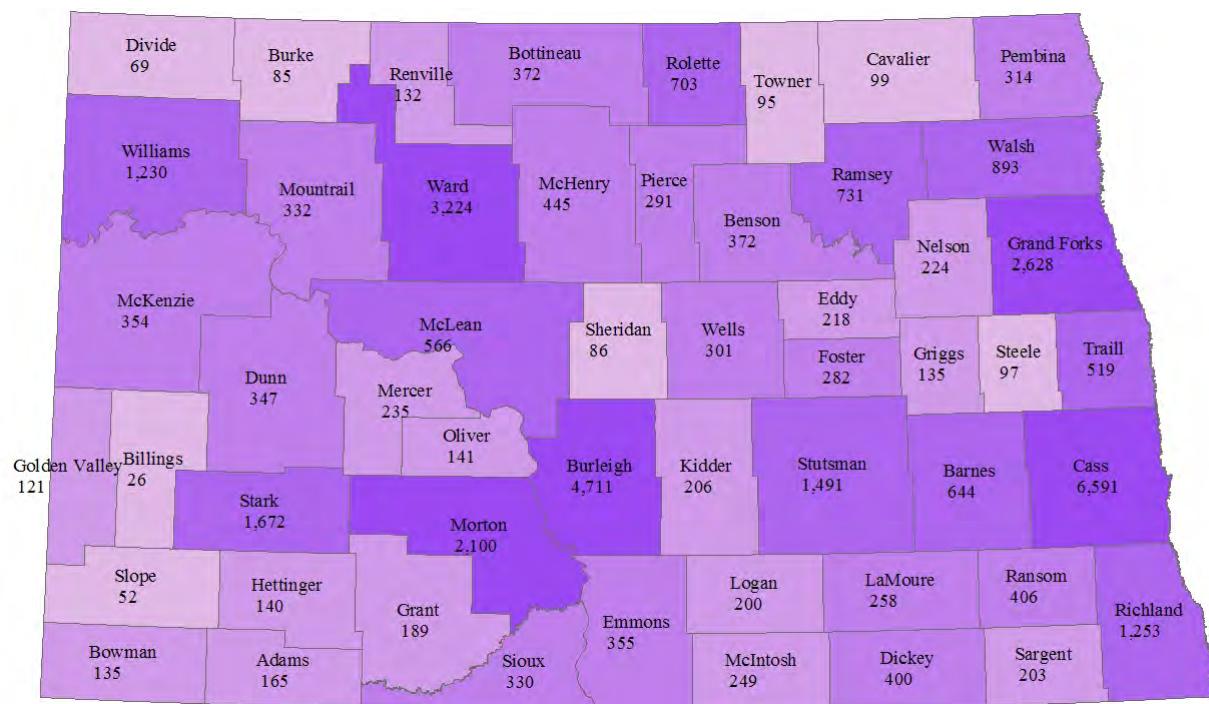

Figure 30. Project Mobility-Impaired Population by County, 2025

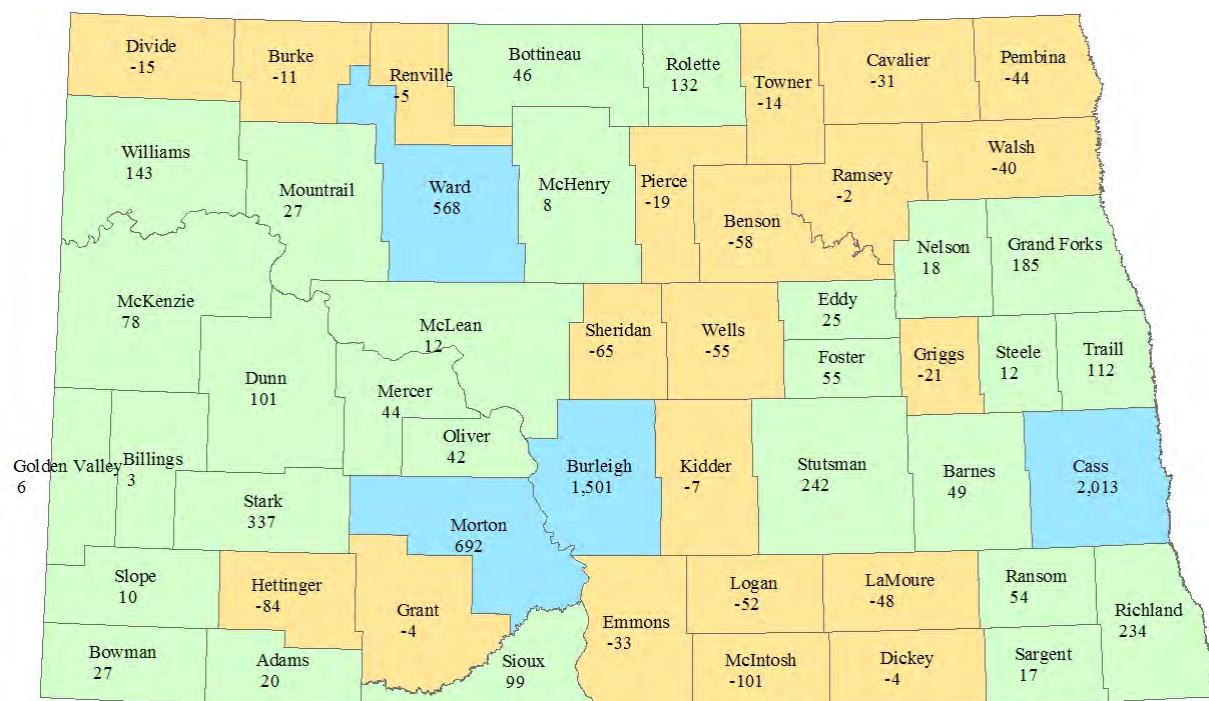

Figure 31. Projected Change in Mobility-Impaired Population by County, 2000 to 2025

Figures 32 and 33 present projections of the number of households without vehicles. The former displays projected values for 2025, the latter the projected change between 2000 and 2025. Fifteen counties are projected to see an increase in the number of households that do not have vehicles. However, most counties are projected to see relatively small changes with only Cass, Burleigh, and Morton counties seeing increases of more than 100 households, while Grand Forks is the only county projected to experience a decrease of more than 100.

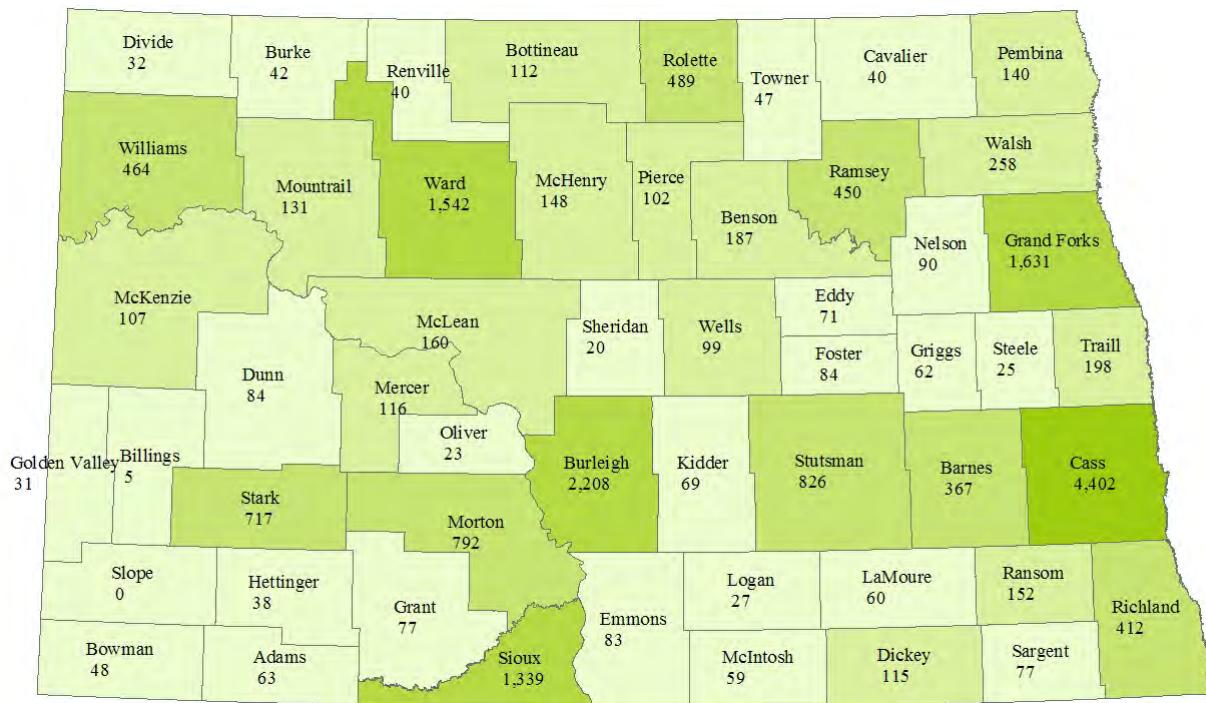

Figure 32. Projected Number of Households without Vehicles by County, 2025

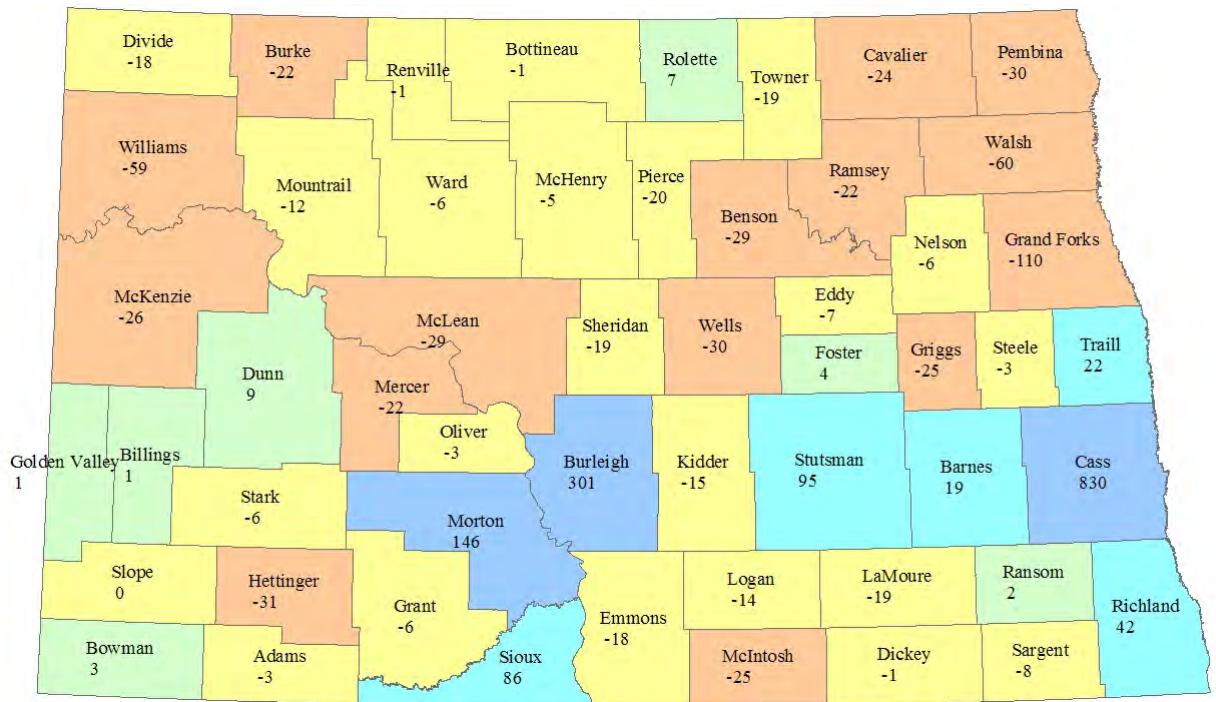

Figure 33. Projected Change in Number of Households without Vehicles by County, 2000 to 2025

Applications of the Data

Significant changes in the demographic makeup of North Dakota are projected to occur between 2000 and 2025. Statewide, the number of seniors and disabled in the state are projected to increase tremendously over the period, while the number of enrolled students age 5 to 19 falls. To make the most of the limited resources available to provide transportation to these traditionally mobility-challenged populations, managers of agencies that provide local transportation, individuals with oversight responsibility of these organizations, and policymakers need to determine what types of service will best meet the needs of these groups. The size and distribution of the populations projected in this study should help the decision-making process.
